

Big-Step Bounded Model Checking for Software

Nishant Sinha,
IBM Research Labs
Bangalore, India

Example: NULL dereference

```
1 class A implements C {
2     List srcs;
3     A(List srcs, Rect b) {
4         init (srcs, b);
5     }
6     void init(List srcs, Rect b) {
7         this.srcs = new Vector ();
8         if (srcs != null) {
9             this.srcs.addAll (srcs);
10        }
11        ★ if (srcs.size() != 0) {...}
12    }
13 }
14 class T extends A {
15     T(List srcs, Rect b) {
16         if (srcs.isEmpty()) return;
17         init(srcs, b);
18     }
19 }
```

```
1 class M extends A {
2     M(C src, C alpha) {
3         List srcs; Rect b;
4         srcs = makeList(src,alpha);
5         b = makeBounds(src,alpha);
6         super(srcs, b);
7     }
8     List makeList(C s1, C s2) {
9         List ret = new ArrayList (2);
10        ret.add(s1);
11        ret.add(s2);
12        return ret;
13    }
14 }
15 class N {
16     void foo(C src, C alpha) {
17         C m = new M(src,alpha);
18         ...
19     }
20 }
```

```

1 class A implements C {
2     List srcs;
3     A(List srcs, Rect b) {
4         init (srcs, b);
5     }
6     void init(List srcs, Rect b) {
7         this.srcs = new Vector ();
8         if (srcs != null) {
9             this.srcs.addAll (srcs);
10        }
11        * if (srcs.size() != 0) {...}
12    }
13 }
14 class T extends A {
15     T(List srcs, Rect b) {
16         if (srcs.isEmpty()) return;
17         init(srcs, b);
18     }
19 }

```

```

1 class M extends A {
2     M(C src, C alpha) {
3         List srcs; Rect b;
4         srcs = makeList(src, alpha);
5         b = makeBounds(src, alpha);
6         super(srcs, b);
7     }
8     List makeList(C s1, C s2) {
9         List ret = new ArrayList (2);
10        ret.add(s1);
11        ret.add(s2);
12        return ret;
13    }
14 }
15 class N {
16     void foo(C src, C alpha) {
17         C m = new M(src, alpha);
18         ...
19     }
20 }

```

Main Software Verification Paradigms

Automated Verification Strategies

Hardware Verification

- Proofs on finite state space
- Iterative fact propagation towards a fixpoint (BDDs)
- Less expressive proof language (propositional logic) enables exact fixpoint computation
- Symbolic search/simulation for finding witnesses using satisfiability solving

Abstract Interpretation

- Proofs on potentially infinite domains (integers)
- Iterative fact propagation towards a fixpoint
- Less expressive proof language
- Allow imprecision/generalization of facts as long as the proof construction does not fail

CEGAR

- Very expressive proof language
- No generic heuristics to obtain fixpoints
- Instead, finitize the set of facts involved in proofs
- Iteratively build spurious proofs and refine them until the actual proof is obtained
- Witnesses are an after-thought

Bounded Model Checking

- Search explicitly/symbolically on part/whole program to find bugs
- Relies on one or more “bounding assumptions”
- Proofs are an after-thought, e.g., by learning from search failures

Bounded Model Checking

- Biere, Clarke et al. '99, originally for hardware verif.
- Initial states I , Transition relation R , Error E

$$I(s_0) \wedge R_1(s_0, s_1) \wedge \dots \wedge R_n(s_{n-1}, s_n) \wedge E(s_n)$$

Check with a SAT/SMT solver, if satisfiable, then the solution (model) maps to an error witness

- Exploit efficient decision procedures for first-order logic, Go light on fixpoints
- Monolithic R does not scale. Need partitioned R .

Partition and Compose Iteratively

- Control/Data flow provides a natural partition

$$\text{(FSM style)} \quad R_k \equiv (pc = k) \Rightarrow (x' = x + 1 \wedge pc' = k + 1)$$

$$R = \bigwedge R_k$$

$$\text{(SSA)} \quad R_1 \equiv (x_1 = x_0 + 1), \quad R_2 \equiv (x_3 = \text{ite}(p, x_1, x_0))$$

$$R = R_1 \wedge R_2$$

- Compose R_k to simulate one or more program paths
 - Check satisfiability after composition to ensure feasibility
- These are fine-grained partitions
 - each BMC step is a **small-step**

Iterative Small-Step Composition

Initial State: $[x \rightarrow x_0, y \rightarrow y_0]$

$[x_0 > 0, x \rightarrow x_0]$

$[x_0 \leq 0, x \rightarrow x_0, ..]$

$[true, y \rightarrow \text{ite}(x_0 > 0, x_0, -x_0)]$

Hierarchical Program Structure

CC77c, SP81, RHS95

Call Graph

Composition of Summaries

2nd order

Control Flow Graphs

Computation of Summaries

1st order

Small Step composition is Bad

- If we do only small-step (or primarily small-step, reuse summaries)
 - will do repeated compositions (re-analyze procedures for different contexts)
 - hard to prioritize between composition choices

Scaling up BMC

What is the granularity of R_k ? **Big-step**

Which state do you start with? **Goal state**

How to choose between non-deterministic
choice of compositions? **Alternate**

Alternate and Learn: Finding Witnesses without Looking All Over

Nishant Sinha, Nimit Singhanian,
Satish Chandra, Manu Sridharan

IBM Research Labs
India, U.S.A.

Computer-Aided Verification, 2012

Our approach: ALTER

- **ALTER**: Goal-Driven Big-Step Composition
 - May be viewed as Scope Expansion around a goal procedure
- Local, One-Time Summaries
- Alternating Exploration starting from Goal
- Learning from Failures

Example: NULL dereference

```
1 class A implements C {
2     List srcs;
3     A(List srcs, Rect b) {
4         init (srcs, b);
5     }
6     void init(List srcs, Rect b) {
7         this.srcs = new Vector ();
8         if (srcs != null) {
9             this.srcs.addAll (srcs);
10        }
11        ★ if (srcs.size() != 0) {...}
12    }
13 }
14 class T extends A {
15     T(List srcs, Rect b) {
16         if (srcs.isEmpty()) return;
17         init(srcs, b);
18     }
19 }
```

```
1 class M extends A {
2     M(C src, C alpha) {
3         List srcs; Rect b;
4         srcs = makeList(src,alpha);
5         b = makeBounds(src,alpha);
6         super(srcs, b);
7     }
8     List makeList(C s1, C s2) {
9         List ret = new ArrayList (2);
10        ret.add(s1);
11        ret.add(s2);
12        return ret;
13    }
14 }
15 class N {
16     void foo(C src, C alpha) {
17         C m = new M(src,alpha);
18         ...
19     }
20 }
```

```

1 class A implements C {
2     List srcs;
3     A(List srcs, Rect b) {
4         init (srcs, b);
5     }
6     void init(List srcs, Rect b) {
7         this.srcs = new Vector ();
8         if (srcs != null) {
9             this.srcs.addAll (srcs);
10        }
11        * if (srcs.size() != 0) {...}
12    }
13 }
14 class T extends A {
15     T(List srcs, Rect b) {
16         if (srcs.isEmpty()) return;
17         init(srcs, b);
18     }
19 }

```

```

1 class M extends A {
2     M(C src, C alpha) {
3         List srcs; Rect b;
4         srcs = makeList(src, alpha);
5         b = makeBounds(src, alpha);
6         super(srcs, b);
7     }
8     List makeList(C s1, C s2) {
9         List ret = new ArrayList (2);
10        ret.add(s1);
11        ret.add(s2);
12        return ret;
13    }
14 }
15 class N {
16     void foo(C src, C alpha) {
17         C m = new M(src, alpha);
18         ...
19     }
20 }

```

A Local Summary

<Side-effects, Call-sites, Error Conditions>

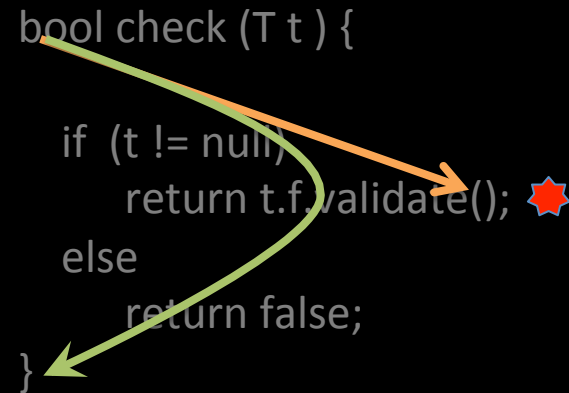

- Abstract away **caller inputs** and **callee side-effects** with fresh variables (Skolems)
- Then, compute a local summary by intra-procedural all-path symbolic execution
- **Fully-precise** modulo caller inputs and callee side-effects

KP05, S08,
CFS09

Example: Local Summary

```
bool check (T t ) {  
    if (t != null)  
        return t.f.validate();★  
    else  
        return false;  
}
```

```
bool check (T t ) {  
    if (t != null)  
        return t.f.validate();★  
    else  
        return false;  
}
```

Call-Site

$(t_0 \neq \text{null}, t \rightarrow t_0)$

Side-effect

$(\text{true}, \text{ret} \rightarrow \text{ite}(t_0 \neq \text{null}, \text{sk}_{\text{validate}}, \text{false}))$

EC

$(t_0 \neq \text{null} \wedge t_0.f = \text{null})$

Computed only ONCE for each procedure !

Composition Strategies

CC77c, SP81, RHS95

Call Graph

Composition of Summaries

Control Flow Graphs

Computation of Summaries

1st and 2nd order composition are Intertwined

Compose with G's summary -> Compute G's summary -> Compose H -> Compute H ...

Big-step Composition Strategies

- **Bottom-up** composition
 - Many irrelevant callees composed (e.g., large number of irrelevant virtual calls)
- **Top-down** composition
 - Many irrelevant callers composed if goal is deep
- None satisfactory, both perform eager, possibly irrelevant compositions
- Need a lazier, focused strategy

CC77c, SP81, RHS95

Alternating Expansion

- **Start** from the goal procedure
 - Pick an **EC** for a goal location
- Now, how do we expand out?
 - **Alternate**: go one caller back, then k-callees forward, further back, then fwd
 - **Forward** expansion (composition): Explore Callees
 - Substitute callee placeholders by **side-effect** summaries
 - **Backward** expansion: Explore Callers
 - Substitute inputs by **call context** summaries
- **Backtrack** if the composition yields no witness
- **Terminate** at an entrypoint

```

1 class A implements C {
2     List srcs;
3     A(List srcs, Rect b) {
4         init (srcs, b);
5     }
6     void init(List srcs, Rect b) {
7         this.srcs = new Vector ();
8         if (srcs != null) {
9             this.srcs.addAll (srcs);
10        }
11        ★ if (srcs.size() != 0) {...}
12    }
13 }
14 class T extends A {
15     T(List srcs, Rect b) {
16         if (srcs.isEmpty()) return;
17         init(srcs, b);
18     }
19 }

```

```

1 class M extends A {
2     M(C src, C alpha) {
3         List srcs; Rect b;
4         srcs = makeList(src, alpha);
5         b = makeBounds(src, alpha);
6         super(srcs, b);
7     }
8     List makeList(C s1, C s2) {
9         List ret = new ArrayList (2);
10        ret.add(s1);
11        ret.add(s2);
12        return ret;
13    }
14 }
15 class N {
16     void foo(C src, C alpha) {
17         C m = new M(src, alpha);
18         ...
19     }
20 }

```

Forward

Backward

No Bug!

```

1 class A implements C {
2     List srcs;
3     A(List srcs, Rect b) {
4         init (srcs, b);
5     }
6     void init(List srcs, Rect b) {
7         this.srcs = new Vector ();
8         if (srcs != null) {
9             this.srcs.addAll (srcs);
10        }
11         if (srcs.size() != 0) {...}
12    }
13 }
14 class T extends A {
15     T(List srcs, Rect b) {
16         if (srcs.isEmpty()) return;
17         init(srcs, b);
18     }
19 }

```

```

1 class M extends A {
2     M(C src, C alpha) {
3         List srcs; Rect b;
4         srcs = makeList(src, alpha);
5         b = makeBounds(src, alpha);
6         super(srcs, b);
7     }
8     List makeList(C s1, C s2) {
9         List ret = new ArrayList (2);
10        ret.add(s1);
11        ret.add(s2);
12        return ret;
13    }
14 }
15 class N {
16     void foo(C src, C alpha) {
17         C m = new M(src, alpha);
18         ...
19     }
20 }

```

Focus on
program fragments
relevant to a bug

Naïve Alternation is not enough

- Naïve alternation does avoid irrelevant compositions partially
 - Depends on variables in the error condition (EC)
 - But still re-visits some irrelevant callers/callees
 - Can we avoid **re-exploring similar failures**?
- Context explosion
 - Potentially, explore exponential number of contexts
 - Can we **exploit sharing** in the call graph?

Learning from Failures

- Proof-relevant procedures
 - Need to explore them at least once
 - **Failure**: alternating exploration into such procedures which finds no feasible path
 - On Failure, **learn Invariants** explaining the failure
- Learn from exploration failures
 - Learning on backtracking
 - The Invariants constitute the **proof of correctness**

Learning from Failures

```
1 class App2 {  
2   void runA ()  
3     {... foo(new A()); ...}  
4   void runB ()  
5     {... foo(new B()); ...}  
6   //classes A, B extend class C  
7   int foo (C c) {  
8     if (*) return bar(c,1);  
9     else return bar(c,2);  
10  }  
11  int bar (C c, int i) {  
12    ★ return c.compute(i);  
13  }  
14 }
```

Learning from Failures

```
1 class App2 {
2   void runA ()
3     {... foo(new A()); ...}
4   void runB ()
5     {... foo(new B()); ...}
6   //classes A, B extend class C
7   int foo (C c) {
8     if (*) return bar(c,1);
9     else return bar(c,2);
10  }
11  int bar (C c, int i) {
12    ★ return c.compute(i);
13  }
14 }
```

Interpolate!

Learning from Failures

- How do we avoid redundant composition?
 - Learn **Caller** and **Callee** invariants from failures
 - Avoid repeating similar failures (compositions) again
 - Direct towards other relevant contexts

ALTER: Implementation

- Implemented over WALA platform
 - Shares codebase with **Snugglesbug** CFS09
 - Precise Summaries using **Intra-procedural Symbolic Execution** with **Merging, Rewriting** for Simplification
 - Incremental Call Graphs, Initial Mod-Ref
 - Triaged NULL dereference warnings from **FindBugs**
 - Open-source **Java** Benchmarks
 - batik (157k), ant (88k), tomcat (163k)
- Generate and Check EC for each warning
- CVC3 for satisfiability, MathSAT5 for interpolants

Experiments: Alternation

Benchmark	WIT?	T(SB)	#FS(SB)	T(NoALT)	MaxD(NoALT)	#FS(NoALT)	T(ALTER)	MaxD(ALTER)	#FS(ALTER)

Edge (NL/L) = num of call graph edges explored **LrnEdges** = num of edges explored with learning

LrnReuse = num of times learned invariants helped

LrnUpdt = num of times learned invariants were updated

Related

- Blast, CPAChecker
- SLAM, SMASH
- Lazy Annotations, Whale, Nested Interpolants
- Calysto, Expanding-Scope Analysis
- CBMC, FSoft DC2 platform
- Corral
- Directed Symbolic Execution

Conclusions

- Big-Step BMC for software
- Key idea: **systematic, alternating** exploration from the potential bug location
 - Controlled big-step compositions
 - **Local summaries** computed only once
 - **Learn** caller/callee invariants from failed explorations
- Evaluation
 - Validated bug warnings on large Java codebases
 - Alternation crucial for efficiency
 - Learning prunes exploration, but may incur cost
- Future Work
 - Better Forward expansion, Better Learning Reuse
