Data Mining and Machine Learning January-April 2023

## D-Separation

- Check if $X \perp Y \mid Z$
- Dependence should be blocked on every trail from $X$ to $Y$
- Each undirected path from $X$ to $Y$ is a sequence of basic trails
- For (a), (b), (c), need $Z$ present
- For (d), need $Z$ absent
- In general, V-structure includes

(d) descendants of the bottom node

■ $x$ and $y$ are D-separated given $z$ if all trails are blocked

- Variation of breadth first search (BFS) to check if $y$ is reachable from $x$ through some trail

■ Extends to sets - each $x \in X$ is D-separated from each $y \in Y$

## Markov blanket

- $M B(X)$ - Markov blanket of $X$
- Parents $(X)$
- Children( $X$ )
- Parents of Children $(X)$
- $X \perp \neg M B(X) \mid M B(X)$

## Computing with probabilistic graphical models

- John and Mary call Pearl. What is the probability that there has been a burglary?
- Want $P(b \mid m, j)$
- $\frac{P(b, m, j)}{P(m, j)}$

■ Use chain rule to evaluate joint probabilities

■ Reorder variables appropriately, topological order of graph

## Computing with probabilistic graphical models

- $P(m, j, b)=P(b) \sum_{e=0}^{1} P(e) \sum_{a=0}^{1} P(a \mid b, e) P(m \mid a) P(j \mid a)$
- Construct the computation tree
- Use dynamic programming to avoid duplicated computations
- However, exact inference is NP-complete, in general
- Instead, approximate inference through sampling

## Approximate inference

- Generate random samples ( $b, e, a, m, j$ ), count to estimate probabilities
- Random samples should respect conditional probabilities
- Fix parents of $x$ before generating $x$
- Generate in topological order
- Generate $b$, e with probabilities $P(b)$ and $P(e)$
- Generate $a$ with probability
 $P(a \mid b, e)$

■ Generate $j, m$ with probabilities $P(j \mid a), P(m \mid a)$

## Approximate inference

- We are interested in $P(b \mid j, m)$

■ Samples with $\neg j$ or $\neg m$ are useless

- Can we sample more efficiently?

## Rejection sampling

- $P($ Rain $\mid$ Cloudy, Wet Grass)
- Topological order
- Generate Cloudy
- Generate Sprinkler, Rain
- Generate Wet Grass

■ If we start with $\neg$ Cloudy, sample is useless

- Immediately stop and reject this sample - rejection sampling
- General problem with low probability situation - many samples are rejected

## Likelihood weighted sampling

- $P($ Rain $\mid$ Cloudy, Wet Grass)

■ Fix evidence Cloudy, Wet Grass true

- Then generate the other variables
- Suppose we generate $c, \neg s, r, w$
- Compute likelihood of evidence:

$$
0.5 \times 0.9=0.45
$$

- 0.45 is likelihood weight of sample

■ Samples $s_{1}, s_{2}, \ldots, s_{N}$ with weights $W_{1}, W_{2}, \ldots W_{N}$

$$
P(C)=.5
$$

| $S$ | $R$ | $P(W)$ |
| :---: | :---: | :---: |
| $t$ | $t$ | .99 |
| $t$ | $f$ | .90 |
| $f$ | $t$ | .90 |
| $f$ | $f$ | .00 |

■ $P(r \mid c, w)=\frac{\sum_{s_{i} \text { has rain }} w_{i}}{\sum_{1 \leq j \leq N} w_{j}}$

## Approximate inference using Markov chains

## Markov chains

- Finite set of states, with transition probabilities between states

■ For us, a state will be an assignment of values to variables

- A three state Markov Chain
- Represent using a transition matrix - stochastic

$$
A=\left[\begin{array}{lll}
0 & \frac{1}{2} & \frac{1}{2} \\
1 & 0 & 0 \\
\frac{1}{2} & \frac{1}{2} & 0
\end{array}\right]
$$

- $P[j]$ is probability of being in state $j$
- Start in state 1 , so initially $P=\left[\begin{array}{l}1 \\ 0 \\ 0\end{array}\right]$

## Markov chains . . .

- After one step:

$$
P^{\top} A=\left[\begin{array}{lll}
1 & 0 & 0
\end{array}\right]\left[\begin{array}{ccc}
0 & \frac{1}{2} & \frac{1}{2} \\
1 & 0 & 0 \\
\frac{1}{2} & \frac{1}{2} & 0
\end{array}\right]=\left[\begin{array}{lll}
0 & \frac{1}{2} & \frac{1}{2}
\end{array}\right]
$$

- After second step:

$$
\left[\begin{array}{lll}
0 & \frac{1}{2} & \frac{1}{2}
\end{array}\right]\left[\begin{array}{ccc}
0 & \frac{1}{2} & \frac{1}{2} \\
1 & 0 & 0 \\
\frac{1}{2} & \frac{1}{2} & 0
\end{array}\right]=\left[\begin{array}{lll}
\frac{3}{4} & \frac{1}{4} & 0
\end{array}\right]
$$

- After $k$ steps, $P[j]$ is probability of being in state $j$
- Continuing our example,
$\left[\begin{array}{ccc}\frac{3}{4} & \frac{1}{4} & 0\end{array}\right] \rightarrow\left[\begin{array}{ccc}\frac{1}{4} & \frac{3}{8} & \frac{3}{8}\end{array}\right] \rightarrow\left[\begin{array}{ccc}\frac{9}{16} & \frac{5}{16} & \frac{1}{8}\end{array}\right]$

## Ergodicity

■ Is it the case that $P[j]>0$ for all $j$ continuously, after some point?

- Markov chain $A$ is ergodic if there is some $t_{0}$ such that for every $P$, for all $t>t_{0}$, for every $j$, $\left(P^{\top} A^{t}\right)[j]>0$.
- No matter where we start, after $t>t_{0}$ steps, every state has a nonzero probability of being visited in step $t$
- Properties of ergodic Markov chains

- There is a stationary distribution $\pi^{*},\left(\pi^{*}\right)^{\top} A=\pi^{*}$
- $\pi^{*}$ is a left eigenvector of $A$
- For any starting distribution $P, \lim _{t \rightarrow \infty} P^{\top} A^{t}=\pi^{*}$

## Ergodicity . . .

- How can ergodicity fail?
- Starting from $i$, we reach a set of states from which there is no path back to $i$
- We have a cycle $i \rightarrow j \rightarrow k \rightarrow i \rightarrow j \rightarrow k \cdots$, so we can only visit some states periodically
- Sufficient conditions for ergodicity
- Irreducibility: When viewed as a directed graph, $A$ is strongly connected
- For all states $i, j$, there is a path from $i$ to $j$ and a path from $j$ to $i$

- Aperiodicity: For any pair of vertices $i, j$, the gcd of the lengths of all paths from $i$ to $j$ is 1
- In particular, paths (loops) from $i$ to $i$ do not all have lengths that are multiples of some $k \geq 2$ prevents bad cycles

## Ergodicity . . .

- Can efficiently approximate $\lim _{t \rightarrow \infty} P^{\top} A^{t}$ by repeated squaring: $P^{\top} A^{2}, P^{\top} A^{4}$,

$$
P^{\top} A^{8}, \ldots, P^{\top} A^{2^{k}}, \ldots
$$

- Mixing time - how fast this converges to $\pi^{*}$

■ Stationary distribution represents fraction of visits to each state in a long enough execution

- Can we create a Markov chain from a Bayesian network so that the stationary distribution is meaningful?

## Approximate inference using Markov chains

■ Bayesian network has variables
$v_{1}, v_{2}, \ldots, v_{n}$
■ Each assignment of values to the variables is a state

- Set up a Markov chain based on these states
- Stationary distribution should assign to state $s$ the probability $P(s)$ in the
 Bayesian network

■ How to reverse engineer the transition probabilities to achieve this?
