

# Software Verification and Abstraction

Rupak Majumdar

# Spreading fast

The worm slowly spread until July 19, when the number of computers attacking networks skyrocketed. Now, the worm is hibernating, ready to re-infect Aug. 1.

# Software is Unreliable

# The Premise

---

Reliability is important

- More computers are used in embedded, networked, safety critical applications
- Cost of failure or fixing bug is high

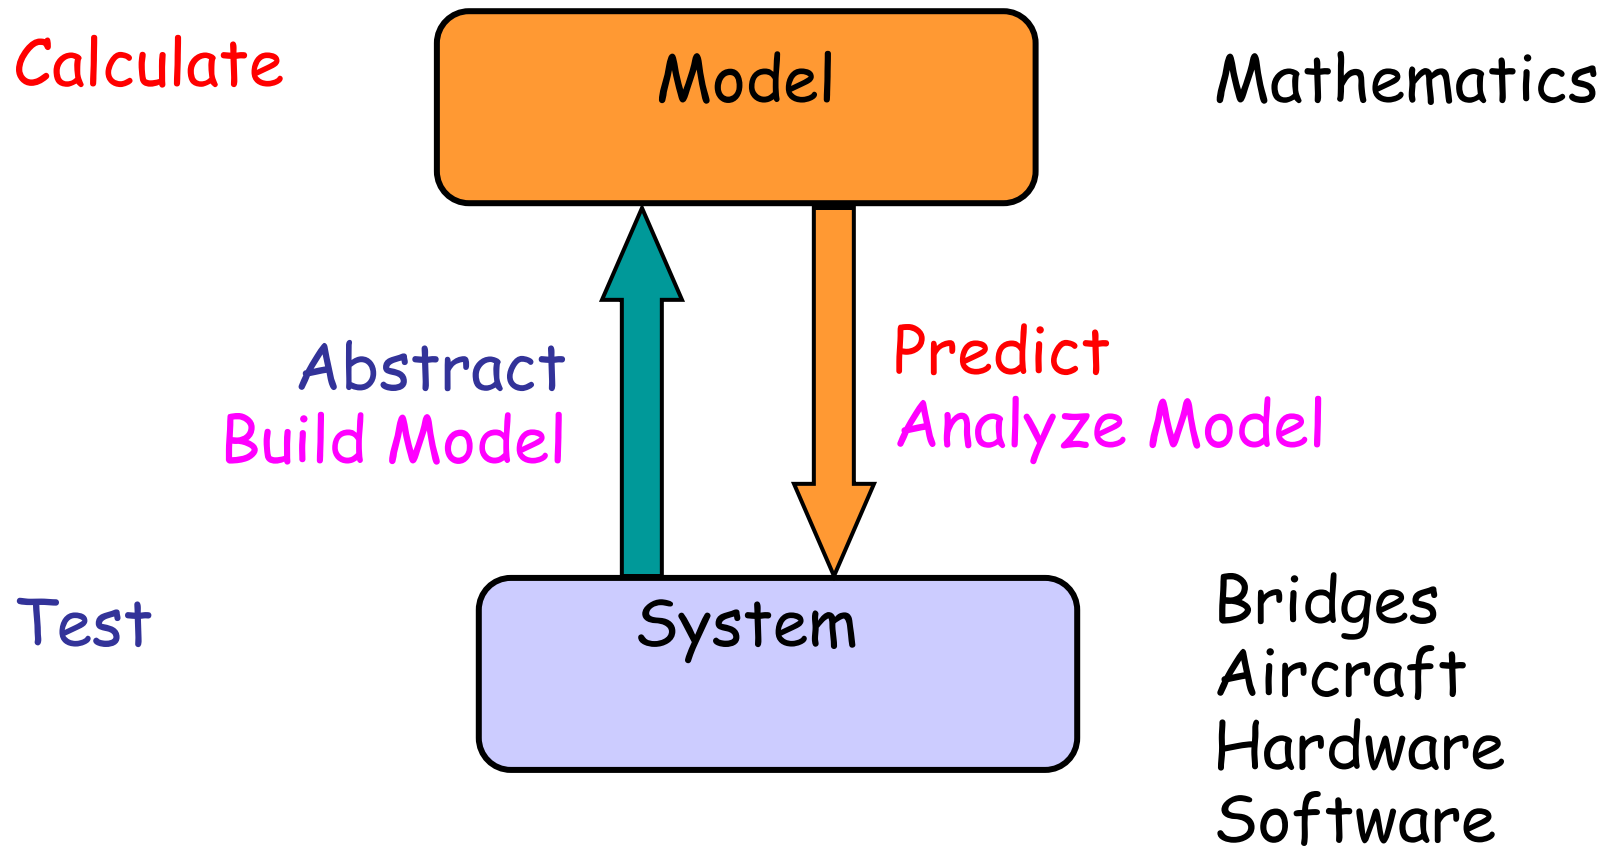

Building large, complex, yet reliable systems is hard

These lectures: What can we do about it?

- Survey research on automatic tools for ensuring a system is “correct”

# Systems and Models

3. Analysis	Solve Equations	?

\* w.r.t. property of interest

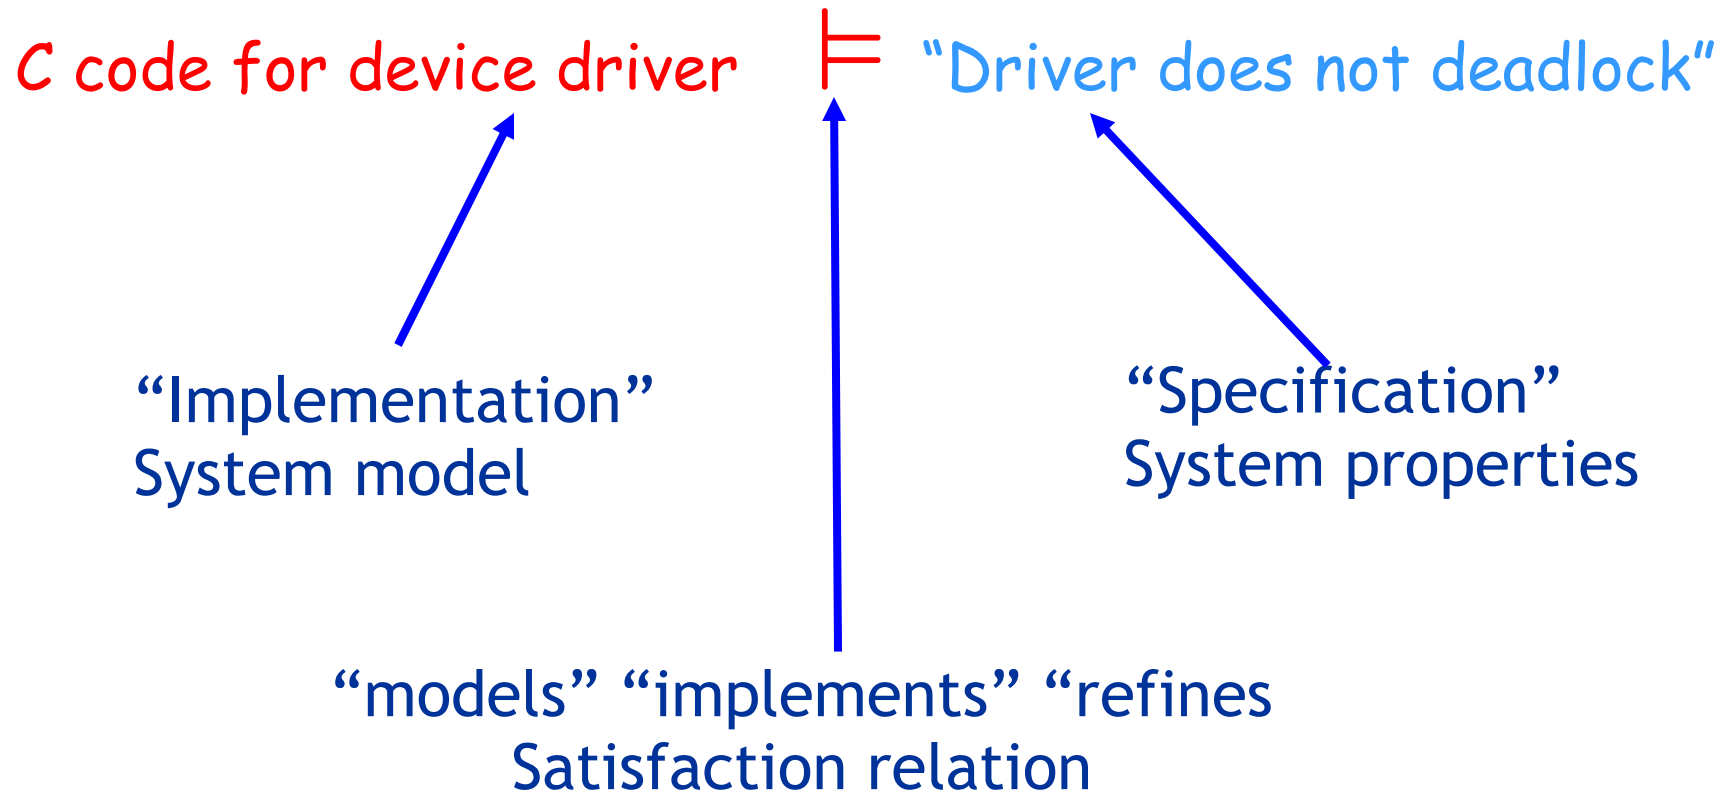

# System Verification Problem

---

# Example

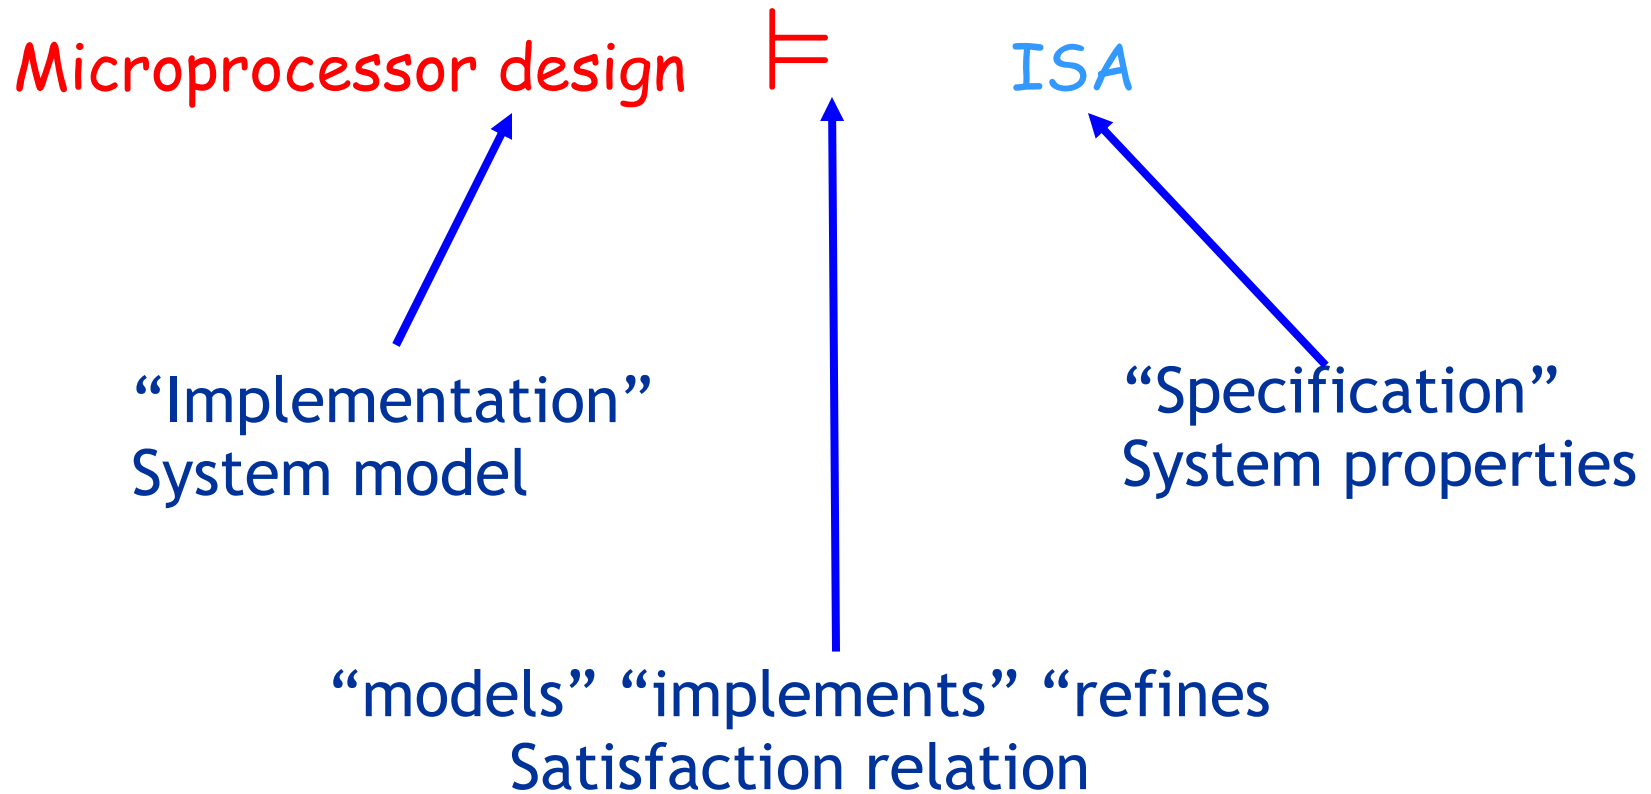

---

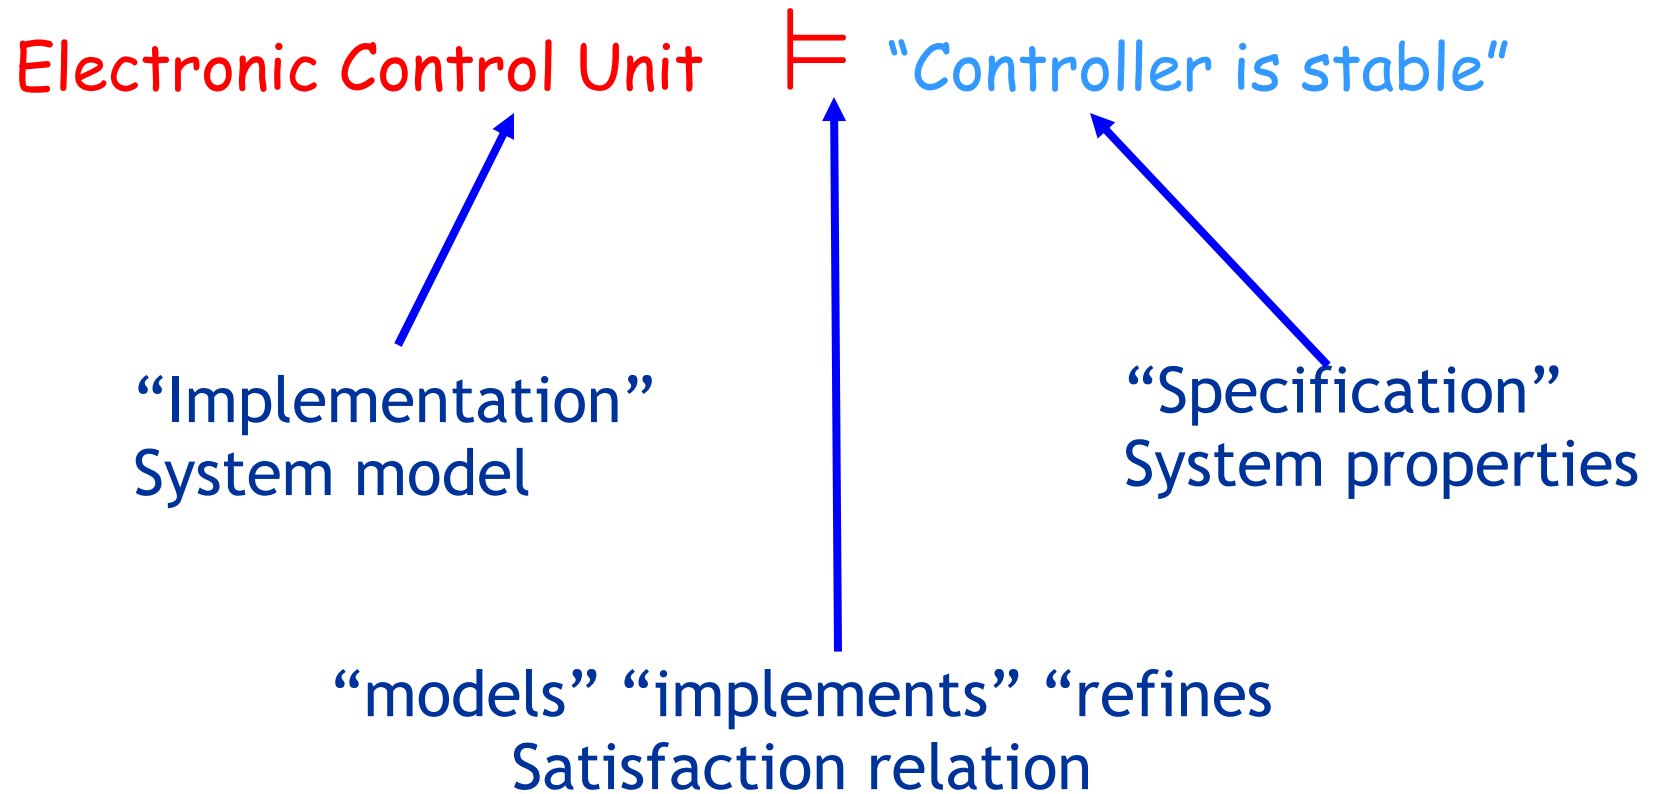

# Example

---

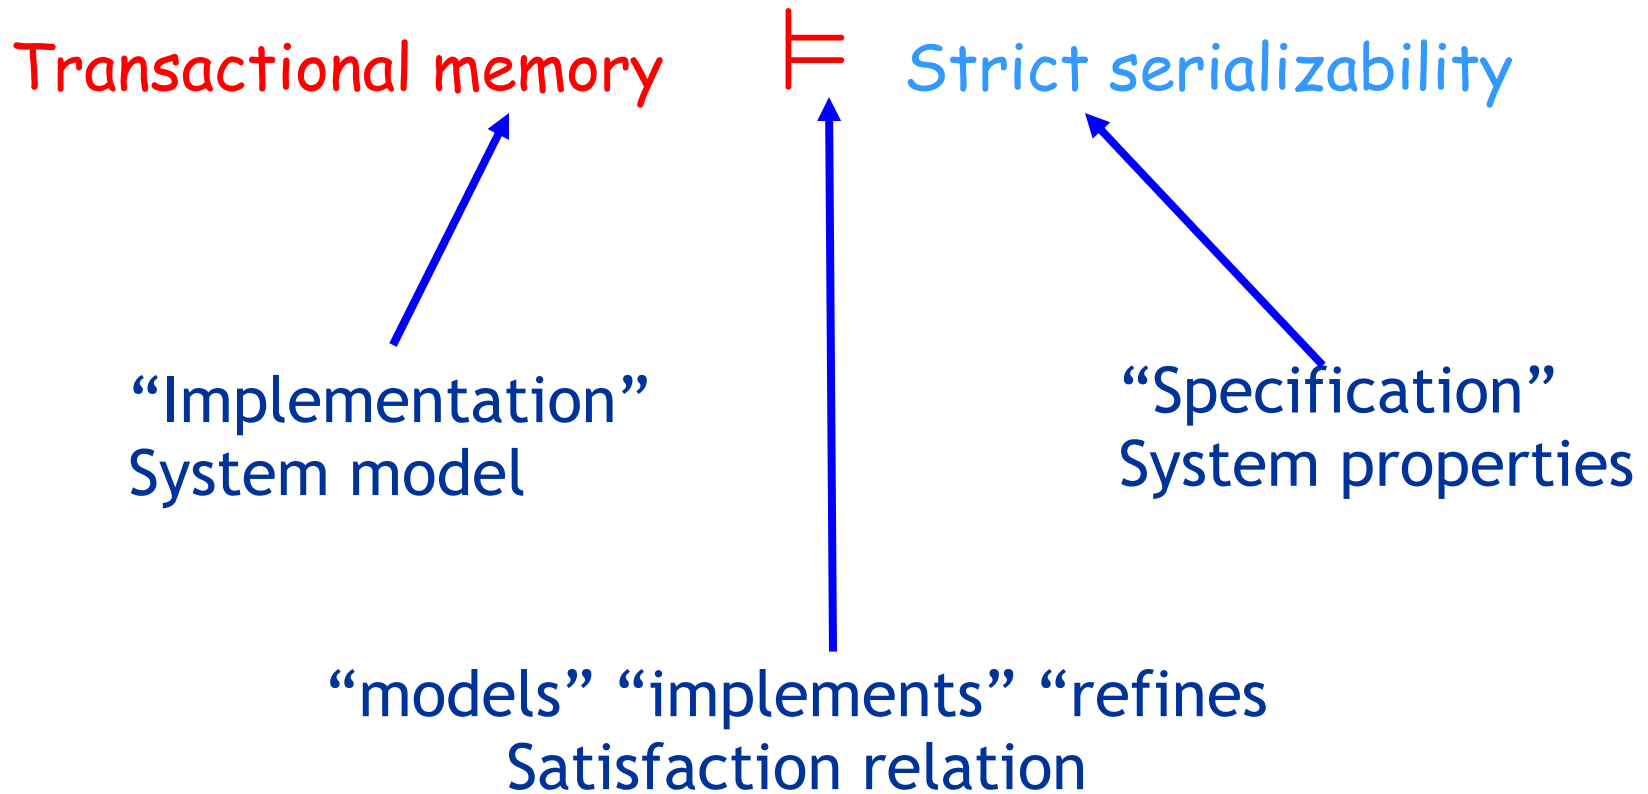

# Example

---

# Example

---

# Lecture 1: Model Checking

## Basic Concepts

Rupak Majumdar

---

**Model checking**, generally interpreted:

Automatic algorithmic techniques for  
system verification which operate on a  
**system model** (semantics)

# Somewhat General View

---

**Model checking**, narrowly interpreted:

Decision procedures for checking if a given Kripke structure is a model for a given formula of a modal logic (CTL or LTL).

Our view **includes**

- Dataflow analysis in compilers
- Symbolic execution based methods

Our view **excludes**

- Language design for ensuring properties
- Proof calculi and interactive theorem proving

---

There are many different model checking algorithms, depending on

- The system model
- The specification formalism

# Discrete Systems Theory

---

**Trajectory:** dynamic evolution of state  
sequence of states

**Model:** generates a set of trajectories  
transition graph

**Property:** assigns boolean values to trajectories  
temporal logic formula

“red and green alternate”

**Algorithm:** compute values of the trajectories  
generated by a model

# Paradigmatic Example: Mutual Exclusion

---

```
loop                                || loop
  out: x1 := 1; last := 1           out: x2 := 1; last := 2
  req: await x2 = 0 or last = 2     req: await x1 = 0 or last = 1
  in:  x1 := 0                       in:  x2 := 0
end loop.                            end loop.
P1                                    P2
```

Property: It is never the case that P1 and P2 are both at `in`

# System Modeling

---

- Various factors influence choice of model
  - State based vs event based
  - Concurrency model
- While the choice of system model is important for ease of modeling in a given situation,

the only thing that is important for model checking is that the system model can be translated into some form of state-transition graph.

- So: Will not focus much on syntactic constructs

# Syntax: Finite State Programs

---

- Parallel composition of C programs, without function calls
- Each variable has a finite range
- We'll write such programs as guarded commands

# Semantics: State Transition Graph

---

$Q$	set of states	$\{q_1, q_2, q_3\}$
$q_0$	initial state	$q_1$
$\rightarrow \subseteq Q \times Q$	transition relation	$q_1 \rightarrow q_2$
$A$	set of atomic observations	$\{a, b\}$
$[ ]: Q \rightarrow 2^A$	observation function	$[q_1] = \{a\}$

# Important Restriction

---

Until notified, restrict attention to  
**finite-state transition systems**

$Q$  is finite

# Example: Mutual Exclusion

---

```
loop                                || loop
  out: x1 := 1; last := 1           out: x2 := 1; last := 2
  req: await x2 = 0 or last = 2     req: await x1 = 0 or last = 1
  in:  x1 := 0                       in:  x2 := 0
end loop.                             end loop.
P1                                     P2
```

3 · 3 · 2 · 2 · 2 = 72 states

# State Explosion Problem

---

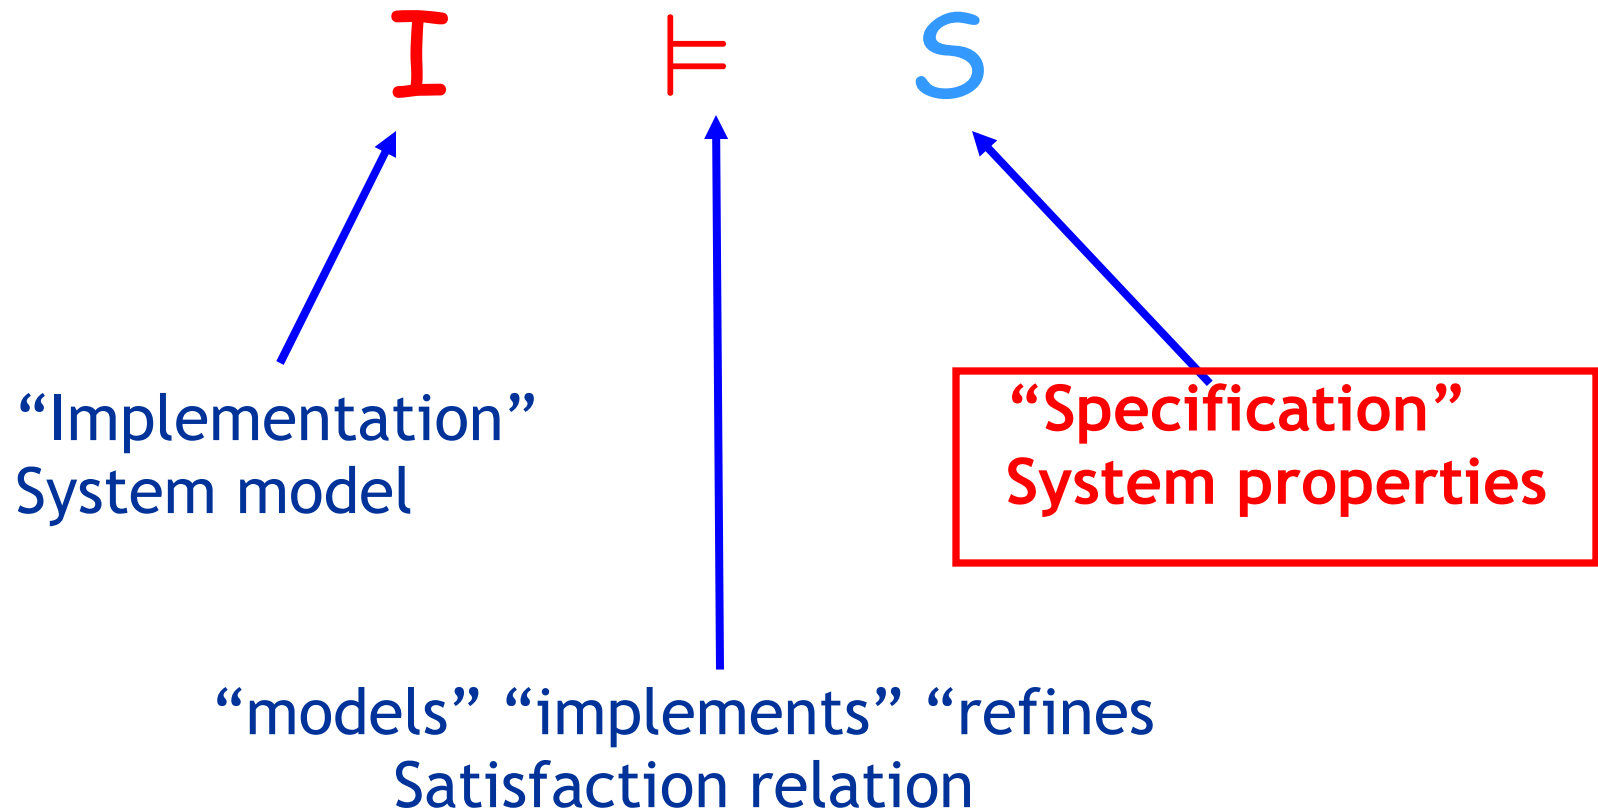

The translation from a system description to a state-transition graph usually involves an exponential blow-up !!!

e.g.,  $n$  boolean variables  $\Rightarrow 2^n$  states

# System Verification Problem

---

# System Properties

---

Some orthogonal dimensions in choosing specification formalisms

1 operational vs. declarative:

automata vs. logic

2 may vs. must:

branching vs. linear time

2 prohibiting bad vs. desiring good behavior:

safety vs. liveness

The three decisions are orthogonal, and they lead to substantially different model-checking problems

# Safety vs Liveness

---

- **Safety**: Something “bad” will never happen
  - Program does not produce bad result  
“partial correctness”
  - *Example: Mutual exclusion*
- **Liveness**: Something “good” eventually happens
  - The program produces a result “termination”
  - *Example: A process wanting to go to the critical section eventually gets in*

# Safety vs Liveness Contd.

---

- **Safety:** those properties whose violation always has a finite witness
  - “if something bad happens on an infinite run, then it happens already on some finite prefix” --- Can be checked on finite runs
- **Liveness:** those properties whose violation never has a finite witness
  - “no matter what happens along a finite run, something good could still happen later” --- Must be checked on infinite runs

# Two Remarks

---

1. The vast majority of properties to be verified are safety
2. While nobody will ever observe the violation of a true liveness property, liveness is a useful abstraction that turns complicated safety into simple liveness

Accordingly, we focus on safety for most of the lectures

# Safety Model Checking

---

- Requirement: The system should always stay within some safe region
- Input: A state transition graph
- Input: A set of good states “invariants”
- Output: “Safe” if all executions maintain the invariant, “Unsafe” otherwise (and a trace)

# From Safety to Reachability

---

- Input: A state transition graph
- Input: A set of bad states
- Output: “Safe” if there is no run from an initial state to any bad state, “Unsafe” otherwise (and a trace)

# Model Checking Algorithm

---

- Graph Search
  - Linear time in the size of the graph
  - Exponential time in the size of the program

# Enumerative Model Checking

---

- Provide access to each state
- For each state, provide access to neighboring states
- Implement classical graph algorithms
  - **Depth-first** or **breadth-first** search
  - Starting from initial states and searching forward for bad states
  - Or starting from bad states and searching backward for initial states

# State Space Explosion

---

- Biggest problem is state space explosion
  - $N$  bits  $\Rightarrow 2^N$  states
- Many heuristics
  - Search on-the-fly,
  - partial order and symmetry reduction
  - Do not store dead variables
- Many successful implementations
  - Spin, Murphi, Verisoft, ... [Protocol verification]

# Symbolic Model Checking

---

- Idea: Work with sets of states, rather than individual states

Given: Transition graph  $G$ , target states  $\sigma^T$   
begin

- $\sigma^R$  = set of Initial states
  - repeat forever
    - if  $\sigma^R \cap \sigma^T \neq \emptyset$  then return “yes”
    - if  $\text{Post}(\sigma^R) \subseteq \sigma^R$  then return “no”
    - $\sigma^R := \sigma^R \cup \text{Post}(\sigma^R)$
- end

Here,  $\text{Post}(\sigma) = \{s' \mid \exists s \in \sigma. s \rightarrow s'\}$

# Encoding Sets through Formulas

---

- Idea: Represent sets of states symbolically, using constraints
- E.g.,  $1 \leq x \leq 100$  represents the 100 states  $x = 1, x = 2, \dots, x = 100$
- Represent both sets of initial states and transition relation implicitly

# Representing States as *Formulas*

$[F]$

states satisfying  $F$   $\{s \mid s \models F\}$

$F$

FO fmla over prog. vars

$[F_1] \cap [F_2]$

$F_1 \wedge F_2$

$[F_1] \cup [F_2]$

$F_1 \vee F_2$

$\overline{[F]}$

$\neg F$

$[F_1] \subseteq [F_2]$

$F_1$  implies  $F_2$

i.e.  $F_1 \wedge \neg F_2$  unsatisfiable

# Symbolic Transition Graph

---

- A transition graph
  - A Formula  $\text{Init}(x)$  representing initial states
  - A Formula  $\text{TR}(x, x')$  representing the transition relation

- Example: C program

$x := e$        $\text{TR}(x, x') : \text{loc} = \text{pc} \wedge \text{loc}' = \text{pc}' \wedge x' = e \wedge \{ y' = y \mid y \neq x \}$

$\text{Assume}(p)$        $\text{TR}(x, x') : \text{loc} = \text{pc} \wedge \text{loc}' = \text{pc}' \wedge p$

# Symbolic Transition Graph

---

- Operations:

- $\text{Post}(X) = \{s' \mid \exists s \in X. s \rightarrow s'\}$   
 $= \exists s. X(s) \wedge \text{TR}(s, s')$

- $\text{Pre}(X) = \{s \mid \exists s' \in X. s \rightarrow s'\}$   
 $= \exists s'. \text{TR}(s, s') \wedge X(s')$

- Can implement using formula manipulations

# Symbolic Model Checking

---

Given: Transition graph  $G$ , target states  $\sigma^T$   
begin

- $\sigma^R$  = Formula representing set of Initial states
  - repeat forever
    - if  $\sigma^R \wedge \sigma^T$  is satisfiable then return “yes”
    - if  $\text{Post}(\sigma^R) \Rightarrow \sigma^R$  then return “no”
    - $\sigma^R := \sigma^R \vee \text{Post}(\sigma^R)$
- end

Here,  $\text{Post}(\sigma)(s') = \exists s. \sigma(s) \wedge \text{TR}(s, s')$

Can be implemented using **decision procedures** for the language of formulas

# Finite State Systems

---

- Symbolic representation in propositional logic
- State described by  $n$  bits  $X$
- A region is a propositional formula with free variables in  $X$
  
- Can implement symbolic operations using propositional formula manipulations

# Example: Mutual Exclusion

---

```
loop          ||          loop
  out: x1 := 1; last := 1    out: x2 := 1; last := 2
  req: await x2 = 0 or last = 2  req: await x1 = 0 or last = 1
  in:  x1 := 0                in:  x2 := 0
end loop.          end loop.
```

Symbolic representation has variables

$pc1, pc2, x1, x2, last$

Initial states:

$pc1=out \wedge pc2=out \wedge x1=0 \wedge x2=0$  No constraint on last

Transition relation:

$pc1=out \wedge x1'=1 \wedge last'=1 \wedge pc2'=pc2 \wedge x2'=x2$

∨ ...

# Additional Desirable Properties

---

- All operations must be efficient in practice
- Should maintain compactness whenever possible
- Canonical representations
  
- Representing initial states and transition relation from the program description should be efficient

# Binary Decision Diagrams

---

- Efficient representations of boolean functions  
[Bryant86]
- Share commonalities
- Ordered BDDs:
  - Fix a linear ordering of the variables in  $X$
  - BDD = DAG, with nodes labeled with boolean variables
  - Each variable occurs 0 or 1 times along a path
  - Paths in the DAG encode assignments to variables
- Extremely successful in hardware verification

# More on Safety Properties

---

- Not all safety properties can be written as invariants on the program state space
- For example, if correctness depends on the order of events
  - Locks can be acquired and released in alternation, it is an error to acquire/release a lock twice in succession without an intermediate release / acquire

# Monitors

---

- Write the ordering of events as an automaton (called the monitor)
- Take the product of the system with the monitor
  - The monitor tracks the sequence of events
  - It goes to a special “bad” state if a bad sequence occurs
- Now we can express the property as an invariant: the monitor state is never bad

# Symbolic Search

---

- Guaranteed to terminate for finite state systems
- And can be applied to infinite state systems as well
  - Although without guarantees of termination in general
  - Application to infinite state requires richer languages for formulas and associated decision procedures

# What about Software?

---

- Can construct an infinite state transition system from a program
- States: The state of the program
  - (stack, heap, pc location)
- Transitions:  $q \rightarrow q'$  iff in the operational semantics, there is a transition of the program from  $q$  to  $q'$
- Initial state: Initial state of the program

# Termination

---

- Each operation can be computed
- But iterating Pre or Post operations may not terminate
- What do we do now?

# Observation

---

- Often, we do not need the exact set of reachable states
  - We need a set of states that separates the reachable states from the bad states

# One Possibility

---

- User gives an estimate (**inductive invariant**)  
A set of states **Inv** such that
  - $\text{Init} \subseteq \text{Inv}$    -  $\text{Inv} \cap \text{bad} = \emptyset$    -  $\text{Post}(\text{Inv}) \subseteq \text{Inv}$
- \* Can show that this implies system is safe (How?)
- \* Given **Inv**, and decision procedures, this procedure is guaranteed to terminate
- This is the idea of **classical loop invariants**
  - Problem: In general, it can be hard to manually construct **Inv**

# Before we proceed

---

- What is the sign of the following product:
  - $12433454628 * 94329545771$  ?

# Idea

---

- One can “abstract” the behavior of the system, and yet reason about certain aspects of the program
- Abstraction:  
-ve \* +ve = -ve

# Model Checking Algorithm

---

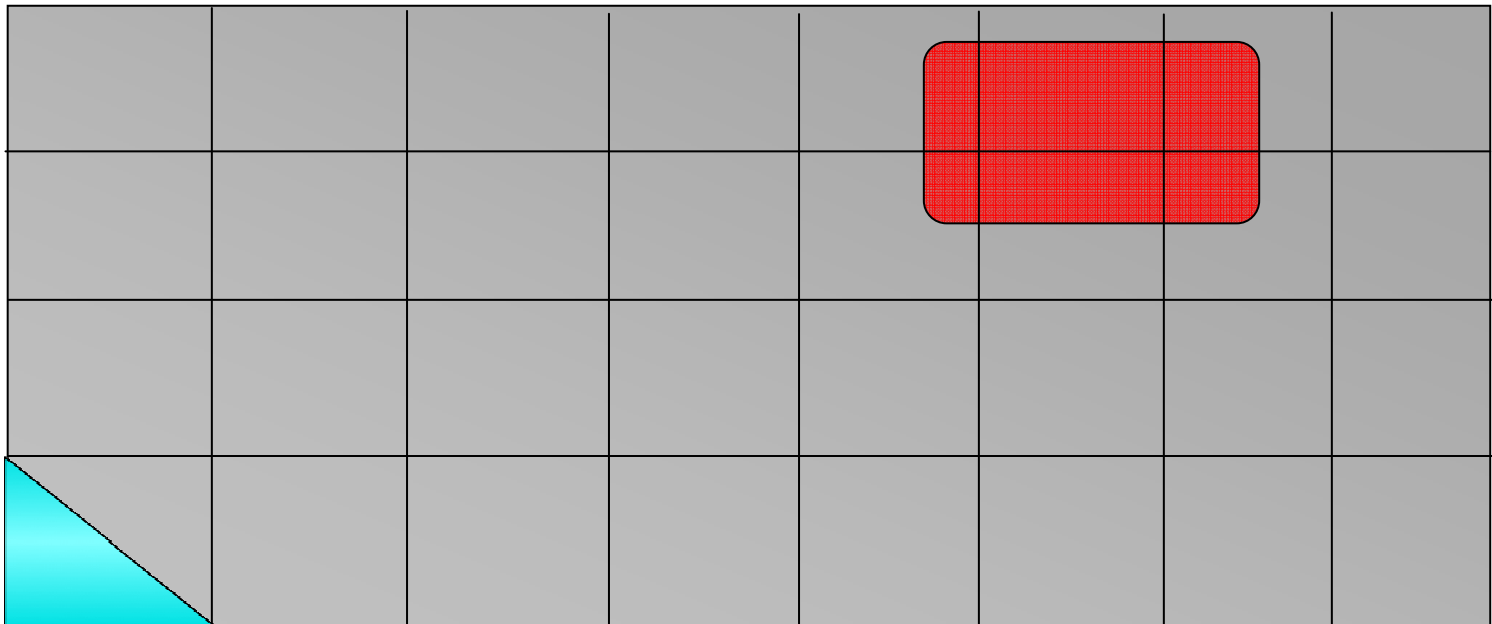

- Graph Search

# Abstract Interpretation

---

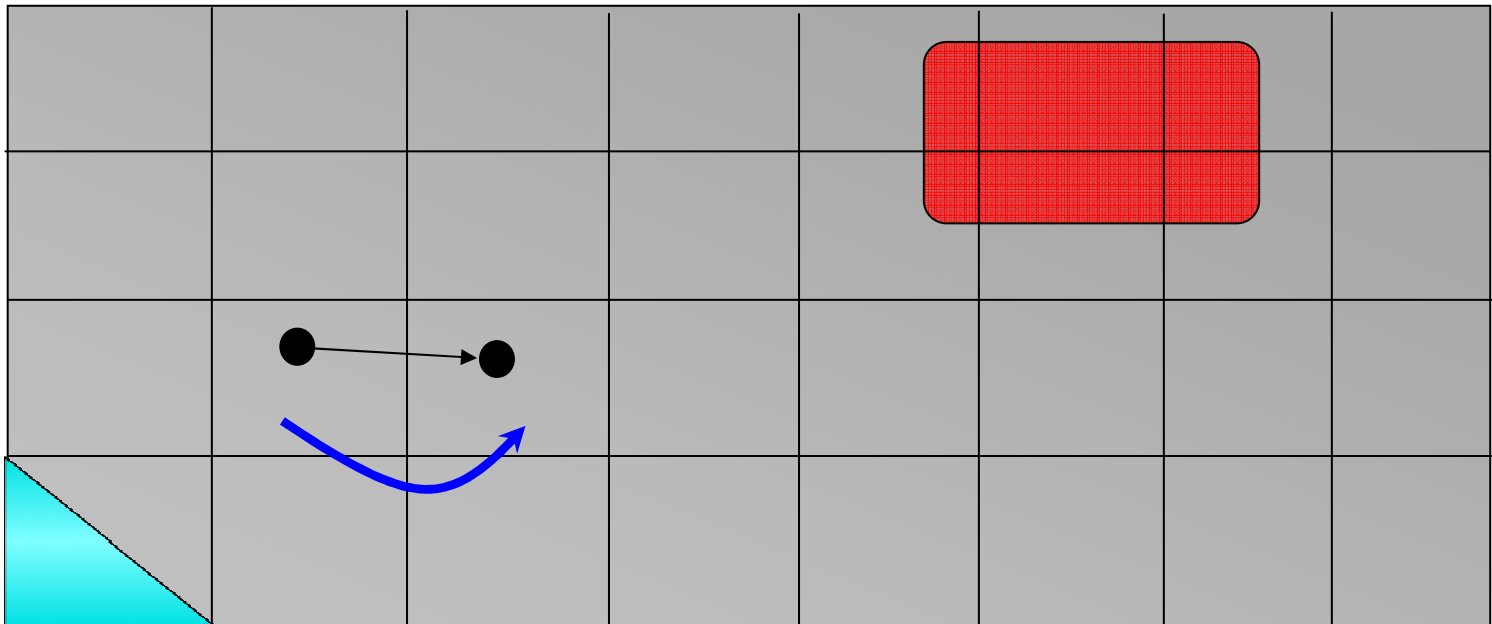

- The state transition graph is large/infinite
- Suppose we put a finite grid on top

# Existential Abstraction

---

- Every time  $s \rightarrow s'$ , we put  $[s] \rightarrow [s']$
- This allows more behaviors

# Abstract Model Checking

---

- Search the abstract graph until fixpoint
  - Can be much smaller than original graph
  - Can be finite, when original is infinite

# Simulation Relations

---

- A relation  $\preceq \subseteq Q \times Q$  is a simulation relation if  $s \preceq s'$  implies
  - $\text{Observation}(s) = \text{Observation}(s')$
  - For all  $t$  such that  $s \rightarrow t$   
there exists  $t'$  such that  $s' \rightarrow t'$   
and  $s' \preceq t'$

Formally captures notion of “more behaviors”  
Implies containment of reachable behaviors

# Main Theorem

---

- $s \preceq [s]$  is a simulation relation
- If an error is unreachable in  $\text{Abs}(G)$  then it is unreachable in  $G$
- Plan:
  1. Find a suitable grid to make the graph finite state
  2. Run the finite-state model checking algorithm on this abstract graph
  3. If abstract graph is safe, say “safe” and stop

# What if the Abstract Graph says Unsafe?

---

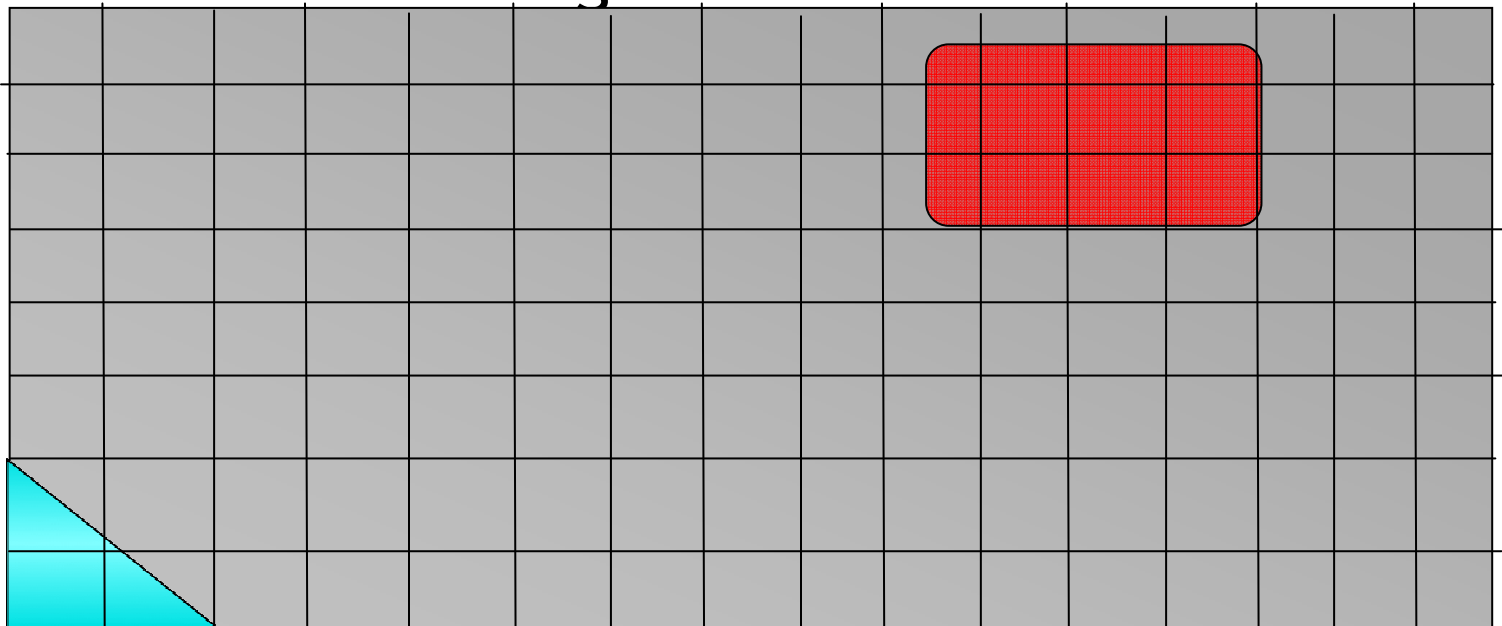

- The error may or may not be reachable in the actual system
  - Stop and say “Don’t know”

# What if the Abstract Graph says Unsafe?

---

- Or, put a finer grid on the state space
- And try again
  - The set of abstract reachable states is smaller
  - Where do these grids come from?

# Grids: Predicate Abstraction

---

- Suppose we fix a set of facts about program variables
  - E.g.,  $old = new$ ,  $lock = 0$ ,  $lock = 1$
- Grid: Two states of the program are equivalent if they agree on the values of all predicates
  - $N$  predicates =  $2^N$  abstract states
- How do we compute the grid from the program?

# Predicate Abstraction

Region Representation: formulas over predicates

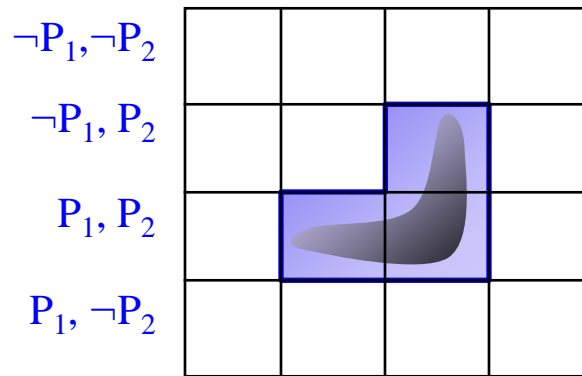

$\neg P_3$   $\neg P_4$   $P_3$   $\neg P_4$

$$P_1 : x = y$$

$$P_2 : z = t + y$$

$$P_3 : x \leq z + 1$$

$$P_4 : *u = x$$

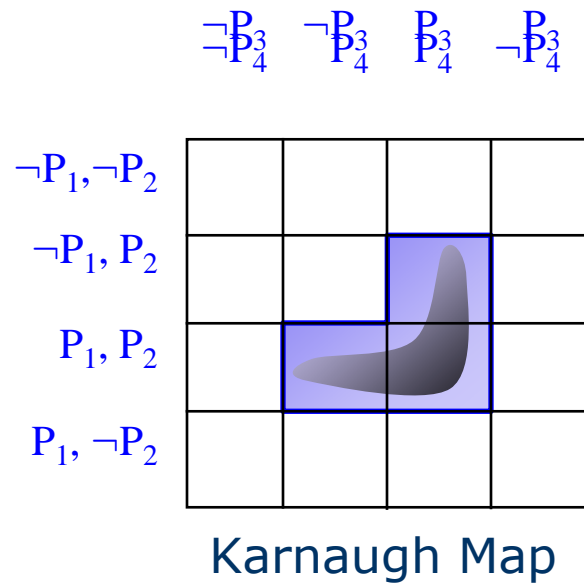

Karnaugh Map

Set of states

**Abstract Set:**  $P_1 P_2 P_4 \vee \neg P_1 P_2 P_3 P_4$

# Predicate Abstraction

---

$$P_1 : x = y$$

$$P_2 : z = t + y$$

$$P_3 : x \leq z + 1$$

$$P_4 : *u = x$$

- Box: abstract variable valuation
- BoxCover(S): Set of boxes covering S
- Theorem prover used to compute BoxCover

# Post#, Pre

**post(S)**

**post#(S)**

- $\text{pre}(S, \text{op}) = \{ s \mid \exists s' \in S. s \rightarrow^{\text{op}} s' \}$  (Weakest Precondition)
- $\text{post}(S, \text{op}) = \{ s \mid \exists s' \in S. s' \rightarrow^{\text{op}} s \}$  (Strongest Postcondition)
- Abstract Operators:  $\text{post}^\#$   
 $\text{post}(S, \text{op}) \subseteq \text{post}^\#(S, \text{op})$

# Computing Post#

- For each predicate  $p$ , check if
  - $S \Rightarrow \text{Pre}(p, \text{op})$  then have a conjunct  $p$
  - $S \Rightarrow \text{Pre}(\neg p, \text{op})$  then have a conjunct  $\neg p$
  - Else have no conjunct corresponding to  $p$
- Use a theorem prover for these queries

# Example

---

- I have predicates
  - lock=0, new=old, lock=1
- My current region is  $\text{lock} = 0 \wedge \text{new} = \text{old}$
- Consider the assignment  $\text{new} = \text{new} + 1$
  
- What is abstract post?

# Example

---

- $WP(\text{new}:=\text{new}+1, \text{lock}=0)$  is  $\text{lock}=0$
- $WP(\text{new}:=\text{new}+1, \text{lock}=1)$  is  $\text{lock}=1$
- $WP(\text{new}:=\text{new}+1, \text{new}=\text{old})$  is  $\text{new}+1=\text{old}$
  
- $\text{lock}=0 \wedge \text{new}=\text{old} \Rightarrow \text{lock} = 0$  YES
- $\text{lock}=0 \wedge \text{new}=\text{old} \Rightarrow \text{lock} \neq 0$  NO
- $\text{lock}=0 \wedge \text{new}=\text{old} \Rightarrow \text{lock} = 1$  NO
- $\text{lock}=0 \wedge \text{new}=\text{old} \Rightarrow \text{lock} \neq 1$  YES
- $\text{lock}=0 \wedge \text{new}=\text{old} \Rightarrow \text{new}+1=\text{old}$  NO
- $\text{lock}=0 \wedge \text{new}=\text{old} \Rightarrow \text{new}+1 \neq \text{old}$  YES
  
- So post is  $\text{lock} = 0 \wedge \text{lock} \neq 1 \wedge \text{new} \neq \text{old}$

# Symbolic Search with Predicates

---

Symbolic representation:

Boolean formulas of (fixed set of) predicates

- Boolean operations: easy
- Emptiness check: Decision procedures
- Post: The abstract post computation algorithm
- Can now implement symbolic reachability search!

# Big Question

---

- Who gives us these predicates?
- Answer 1: The user
  - Manual abstractions
    - Given a program and property, the user figures out what are the interesting predicates
  - Dataflow analysis
    - For “generic” properties, come up with a family of predicates that are likely to be sufficient for most programs

# Abstract Interpretation

---

- Abstract model checking is formalized through abstract interpretation
  - Formalizes and unifies semantics-based program analysis

# More Approximations

---

- Many program dataflow analyses do not perform exact reachability analysis on the abstract state space
- Instead, use the structure of the control flow graph to further approximate the result

# Example: Flow Sensitive Analysis

---

- For each control flow node, keep track of the set of reachable states (along any program path) to that node
  - Information may be lost at merge points by abstracting  $\vee$  by something coarser
- Assumption: All paths of the control flow graph can be executed
  - Ignore conditional statements

# Flow Insensitive Analysis

---

- Even more approximate
- Disregard the order of operations in the program!
- Much faster analysis than abstract model checking
  - But results are much cruder of course!
  - Can still be useful: e.g., primary way to perform alias analysis

---

When I run a model checker, it goes to compute the result and never comes back. When I run a dataflow analysis, it comes back immediately and says “Don’t know”!

- Patrick Cousot

# Questions?

---

Lecture 2:  
Software Model Checking  
and  
Counterexample-Guided Refinement

Rupak Majumdar

# Recap

---

- Model checking is an algorithmic technique to verify properties of systems
- In conjunction with abstractions, can be effective in proving subtle properties
- Today: Consider the problem of abstract model checking of (sequential) software implementations

# Setting: Property Checking

---

- Programmer gives **partial** specifications
- Code checked for consistency w/ spec
- Different from program correctness
  - Specifications are not complete
  - Is there a complete spec for Word ? Emacs ?

# Interface Usage Rules

---

- Rules in documentation
  - Order of operations & data access
  - Resource management
  - Incomplete, unenforced, wordy
- Violated rules  $\Rightarrow$  bad behavior
  - System crash or deadlock
  - Unexpected exceptions
  - Failed runtime checks

# Property 1: Double Locking

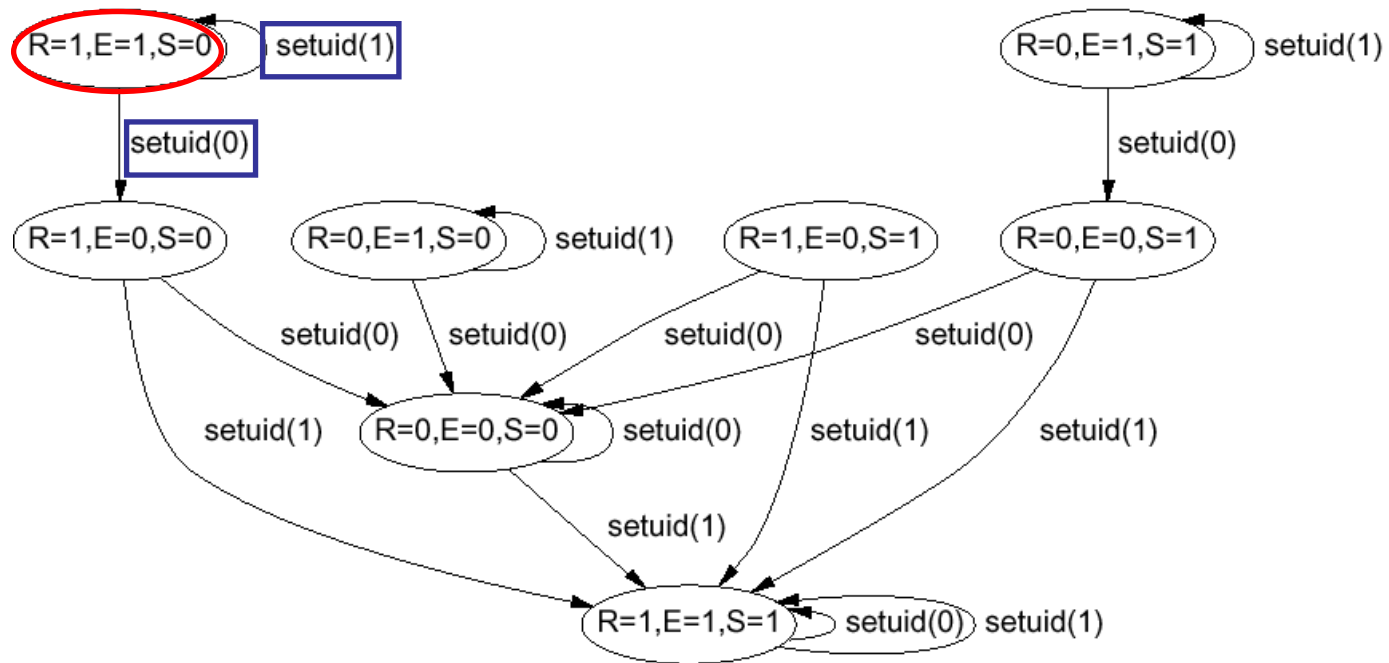

---

*“An attempt to re-acquire an acquired lock or release a released lock will cause a **deadlock**.”*

Calls to **lock** and **unlock** must **alternate**.

# Property 2: Drop Root Privilege

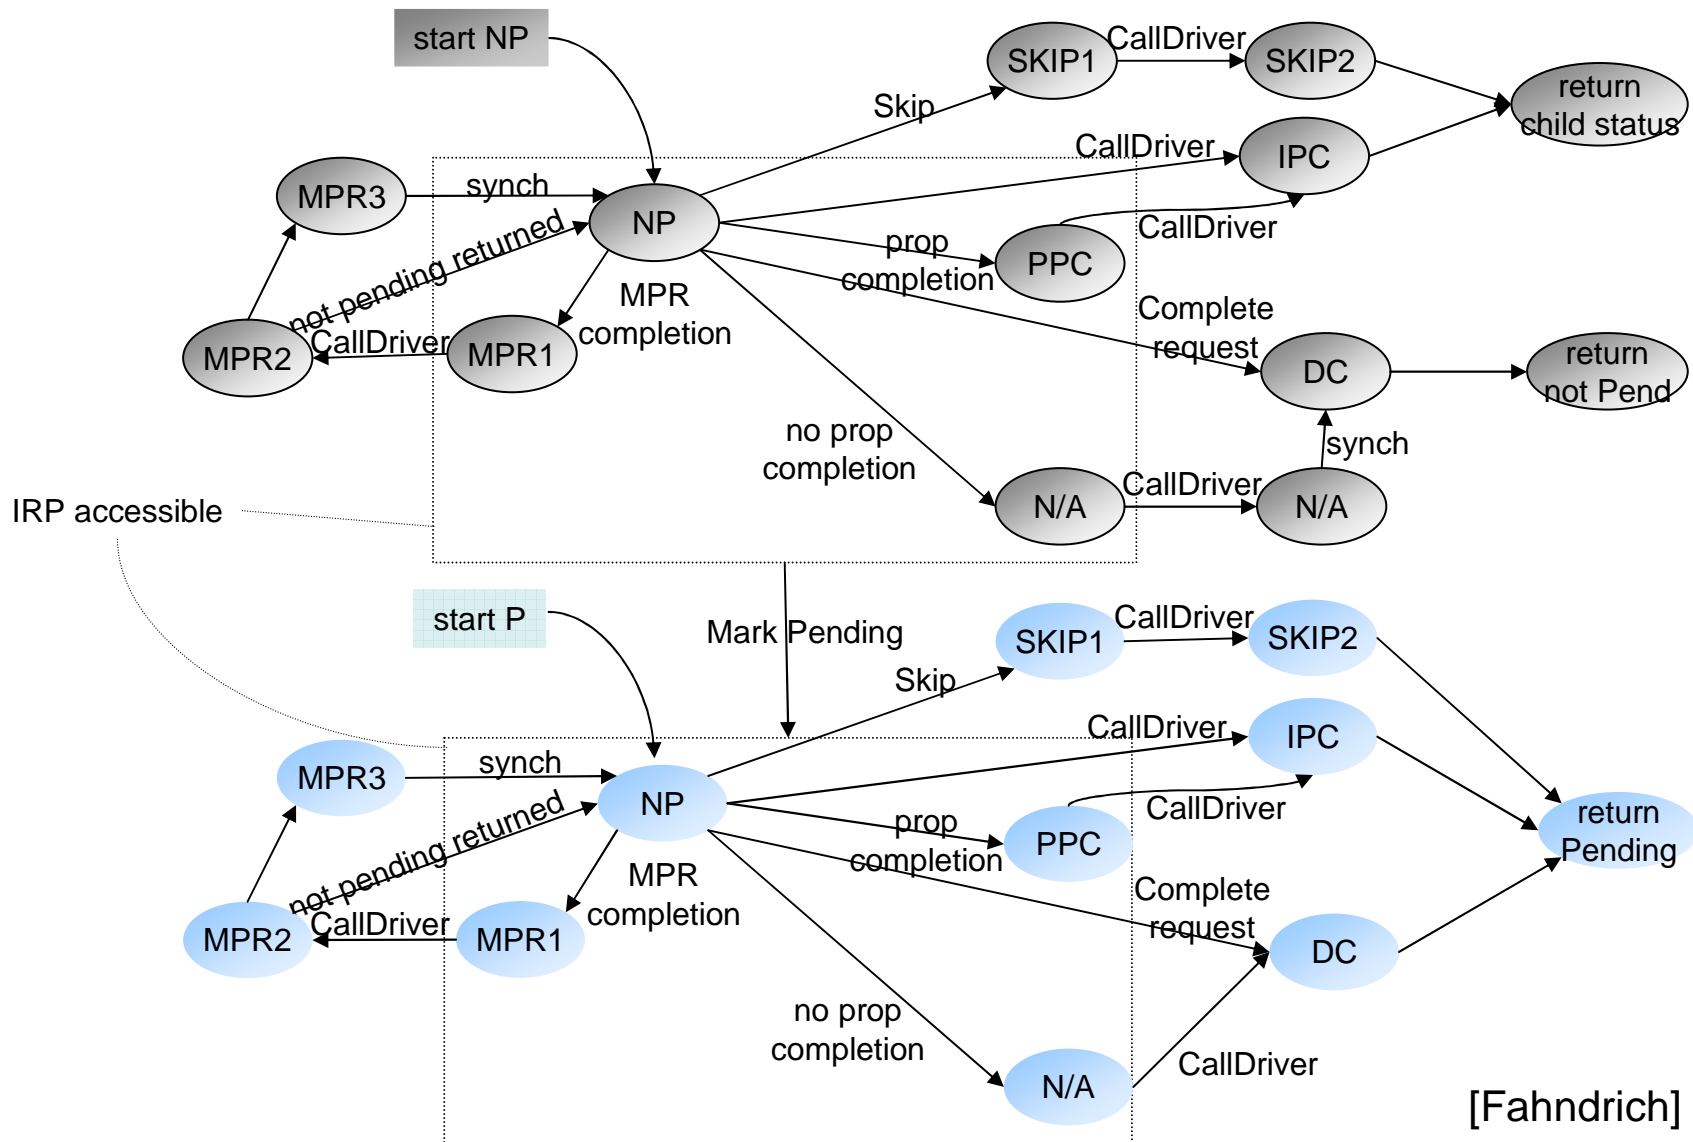

[Chen-Dean-Wagner '02]

*“User applications must not run with root privilege”*

When **execv** is called, must have **suid  $\neq$  0**

# Property 3 : IRP Handler

# Does a given usage rule hold?

---

- Undecidable!
  - Equivalent to the halting problem
- Restricted computable versions are prohibitively expensive (PSPACE)
- Why bother ?
  - Just because a problem is undecidable, it doesn't go away!

# Example

---

```
Example ( ) {  
1: do{  
    lock();  
    old = new;  
    q = q->next;  
2:    if (q != NULL){  
3:        q->data = new;  
        unlock();  
        new ++;  
    }  
4: } while(new != old);  
5: unlock ();  
    return;  
}
```

# What a program *really* is...

## State

$pc$   3  
 $lock$   ●  
 $old$   5  
 $new$   5  
 $q$   0x133a

```

3: unlock();
   new++;
4: } ...
    
```

$pc$   4  
 $lock$   ○  
 $old$   5  
 $new$   6  
 $q$   0x133a

```

Example ( ) {
1: do{
   lock();
   old = new;
   q = q->next;
2:   if (q != NULL){
3:     q->data = new;
       unlock();
       new ++;
   }
4: } while(new != old);
5: unlock ();
   return;}
    
```

# The Safety Verification Problem

Is there a **path** from an **initial** to an **error** state ?

**Problem:** Infinite state graph

**Solution :** Set of states  $\simeq$  logical formula

# Idea 1: Predicate Abstraction

---

- Predicates on program state:
  - lock*
  - old = new*
- States satisfying **same** predicates are **equivalent**
  - Merged into one **abstract state**
- #abstract states is **finite**

# Abstract States and Transitions

# Analyze Abstraction

---

Analyze finite graph

**Over** Approximate:

Safe  $\Rightarrow$  System Safe

No **false negatives**

**Problem**

Spurious **counterexamples**

# Idea 2: Counterex.-Guided Refinement

---

## Solution

Use spurious **counterexamples** to **refine** abstraction !

# Idea 2: Counterex.-Guided Refinement

---

## Solution

Use spurious **counterexamples** to **refine** abstraction

1. **Add predicates** to distinguish states across **cut**

Imprecision due to **merge**

# Iterative Abstraction-Refinement

---

[Kurshan et al 93] [Clarke et al 00]  
[Ball-Rajamani 01]

## Solution

Use spurious **counterexamples**  
to **refine** abstraction

1. Add predicates to distinguish states across **cut**
2. Build **refined** abstraction  
-eliminates counterexample
3. **Repeat** search  
Till real counterexample  
or system proved safe

# Lazy Abstraction

---

# Problem: Abstraction is Expensive

---

Reachable

## Problem

#abstract states =  $2^{\text{\#predicates}}$   
Exponential Thm. Prover queries

## Observe

Fraction of state space reachable  
#Preds ~ 100's, #States ~  $2^{100}$ ,  
#Reach ~ 1000's

# Solution 1: Only Abstract Reachable States

---

Safe

## Problem

#abstract states =  $2^{\text{\#predicates}}$   
Exponential Thm. Prover queries

## Solution

Build abstraction **during** search

# Solution2: Don't Refine Error-Free Regions

---

## Problem

#abstract states =  $2^{\text{\#predicates}}$   
Exponential Thm. Prover queries

## Solution

Don't refine error-free regions

# Key Idea: Reachability Tree

---

## Unroll Abstraction

1. Pick tree-node (=abs. state)
2. Add children (=abs. successors)
3. On **re-visiting** abs. state, **cut-off**

## Find min infeasible suffix

- Learn new predicates
- Rebuild subtree with new preds.

# Key Idea: Reachability Tree

Error Free

## Unroll Abstraction

Refinement

Predicates: LOCK, new==old

# #Predicates grows with program size

---

```
while(1){  
T ● 1: if (p1) lock() ;  
F   if (p1) unlock() ;  
    ...  
T ● 2: if (p2) lock() ;  
    if (p2) unlock() ;  
    ...  
  n: if (pn) lock() ;  
    if (pn) unlock() ;  
}
```

Tracking **lock** not enough

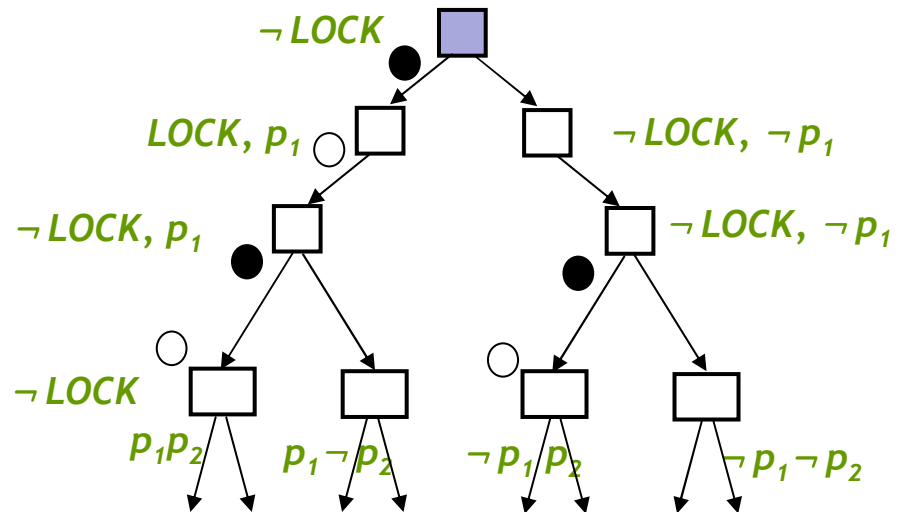

## Problem:

$p_1, \dots, p_n$  needed for verification

Exponential reachable abstract states

# #Predicates grows with program size

```
while(1){  
  1: if (p1) lock() ;  
    if (p1) unlock() ;  
    ...  
  2: if (p2) lock() ;  
    if (p2) unlock() ;  
    ...  
  n: if (pn) lock() ;  
    if (pn) unlock() ;  
}
```

**2<sup>n</sup> Abstract States**

## Problem:

$p_1, \dots, p_n$  needed for verification

Exponential reachable abstract states

# Predicates useful *locally*

```
while(1){  
   $p_1$  { 1: if (p1) lock() ;  
        if (p1) unlock() ;  
        ...  
  }  
   $p_2$  { 2: if (p2) lock() ;  
        if (p2) unlock() ;  
        ...  
  }  
  ...  
   $p_n$  { n: if (pn) lock() ;  
        if (pn) unlock() ;  
  }  
}
```

**2n** Abstract States

**Solution:** Use predicates **only** where needed

Using **Counterexamples:**

**Q1.** Find **predicates**

**Q2.** Find **where** predicates are needed

# Lazy Abstraction

---

**Problem:** #Preds grows w/ Program Size

**Solution:** Localize pred. use, find where preds. needed

# Counterexample Traces

```

Global Predicate use

Ex:  $2^n$  states

Verification scales ...

# Question: When Do Interpolants Exist?

---

- Craig's Theorem guarantees existence for **first order logic**
- But we are interpreting formulas over theories (arithmetic, theories of data structures)

# The Good News

---

- Interpolants always exist for **recursively enumerable theories**
  - The proof is a simple application of compactness
- So: interpolants exist for Presburger arithmetic, sets with cardinality constraints, theory of lists, (quantifier-free) theory of arrays, multisets, ...

# The Bad News

---

- “The proof is a simple application of compactness”
  - May be **algorithmically inefficient**
  - **Daunting engineering task** to construct interpolating decision procedure for each individual theory

# An Alternate Path: Reduction

---

- Want to **compile formulas** in a new theory to formulas in an old theory such that interpolation in the old theory imply interpolation in the new theory
  - **T reduces to R**: can compile formulas in theory **T** to formulas in theory **R**
    - And use decision procedures for **R** to answer decision questions for **T**
- 
- Technically: Given theories **T** and **R**, with  $R \subseteq T$ , a reduction is a computable map  $\mu$  from **T** formulas to **R** formulas such that for any **T**-formula  $\phi$ :
    - $\phi$  and  $\mu(\phi)$  are **T**-equivalent
    - $\phi$  is **T**-satisfiable iff  $\mu(\phi)$  is **R**-satisfiable

# Example: Theory of Sets

---

Theory of sets reduces to theory of equality with uninterpreted functions

$$x = y \quad \forall e. e \in x \Leftrightarrow e \in y$$

$$x = \emptyset \quad \forall e. e \notin x$$

$$x = U \quad \forall e. e \in x$$

$$x = \{e\} \quad e \in x \wedge \forall e'. e' \in x \Rightarrow e = e'$$

$$x = y \cup z \quad \forall e. e \in x \Leftrightarrow e \in y \vee e \in z$$

$$x = y \cap z \quad \forall e. e \in x \Leftrightarrow e \in y \wedge e \in z$$

# Example: Theory of Multisets

---

Theory of multisets reduces to the combination theory of equality with uninterpreted functions and linear arithmetic

$$x = y \quad \forall e. \text{count}(x, e) = \text{count}(y, e)$$

$$x = \emptyset \quad \forall e. \text{count}(x, e) = 0$$

$$x = [(e, n)] \quad \text{count}(x, e) = \max(0, n)$$

$$\wedge \forall e'. e' \neq e \Rightarrow \text{count}(x, e') = 0$$

$$x = y \uplus z \quad \forall e. \text{count}(x, e) = \text{count}(y, e) + \text{count}(z, e)$$

$$x = y \cup z \quad \forall e. \text{count}(x, e) = \max(\text{count}(y, e), \text{count}(z, e))$$

$$x = y \cap z \quad \forall e. \text{count}(x, e) = \min(\text{count}(y, e), \text{count}(z, e))$$

# Reduction and Interpolation

---

$\Psi^-$  and  $\Psi^+$  in Theory  $T$

Reduction from  $T$  to  $R$

$\Phi^-$  and  $\Phi^+$  in Theory  $R$

Interpolate in  $R$

Interpolant  $\alpha$  in  
Theory  $R$  as well as  $T$

Eliminate quantifiers in  $T$  or  $R$

Quantifier-free  
interpolant

# Reduction Theorem

---

- Interpolants for the theory of **arrays**, **sets**, and **multisets** can be computed by reduction to the combination theory of linear arithmetic and equality with uninterpreted functions
  - We already have interpolating decision procedures for this latter theory

# Lazy Abstraction

**Problem:** #Preds grows w/ Program Size

**Solution:** Localize pred. use, find where preds. needed

# So far ...

---

## Lazy Abstraction

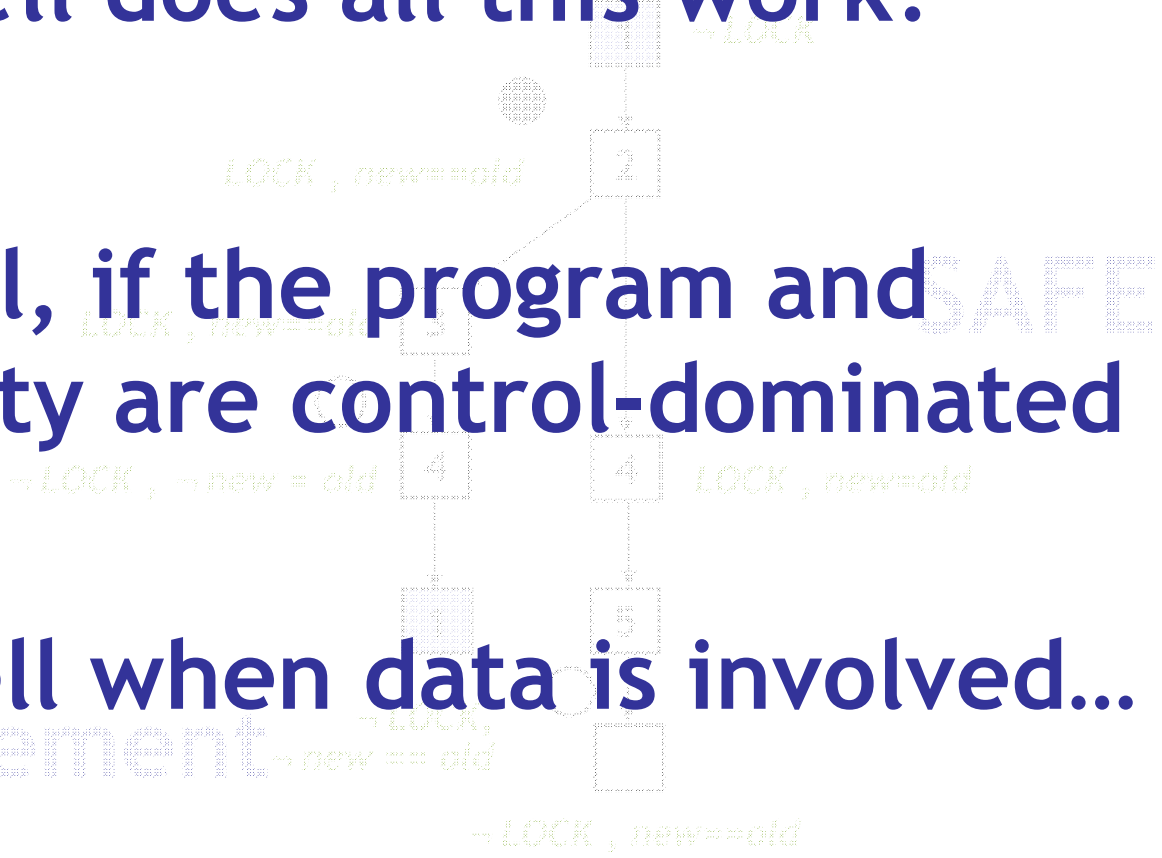

- **Predicates:**
    - Abstract infinite program states
  - **Counterexample-guided Refinement:**
    - Find predicates tailored to prog, property
1. **Abstraction** : Expensive  
**Reachability Tree**
  2. **Refinement** : Find predicates, use locations  
**Proof** of unsat of TF + **Interpolation**

---

So how well does all this work?

```
Sample ( ) {  
1: do {  
    q = q->next;  
2:   if (q != NULL) {  
3:     q->data = new;  
    unlock();  
    new = 1;  
4:   } while (q != NULL);  
5: unlock();  
}
```

Quite well, if the program and property are control-dominated

Not so well when data is involved..

Predicates:  $\text{LOCK}, \text{new} == \text{old}$

# Refinement Failure: Unrolling Loops

---

```
x = 0; y = 50;
while ( x < 100 ) {
    if ( x >= 50 ) y = y + 1;
    x = x + 1;
}
assert( y == 100 );
```

- **counterexample:**  
x=0; y=50; x>=100; y==100  
refinement: x==0
- **counterexample:**  
x=0; y=50; x<100; x=x+1; x>=100; y==100  
refinement: x==1
- **counterexample:**  
x=0; y=50; x<100; x=x+1; x<100; x=x+1;  
x>=100; y==100  
refinement: x==2
- ...

# Refinement Failure: Unfolding Arrays

```
for (i=0; i<n; i++) {  
    a[i]=i;  
}  
  
for (j=0; j<n; j++) {  
    assert( a[j]==j );  
}
```

- counterexample:

i=0; i<n; a[i]=i; i++; i>=n;  
j=0; j<n; a[j]!=j  
refinement: a[0]==0

- counterexample:

i=0; i<n; a[i]=i; i++; i<n; a[i]=i; i++; i>=n;  
j=0; j<n; a[j]==j; j++; j<n; a[j]!=j  
refinement: a[1]==1

- ...

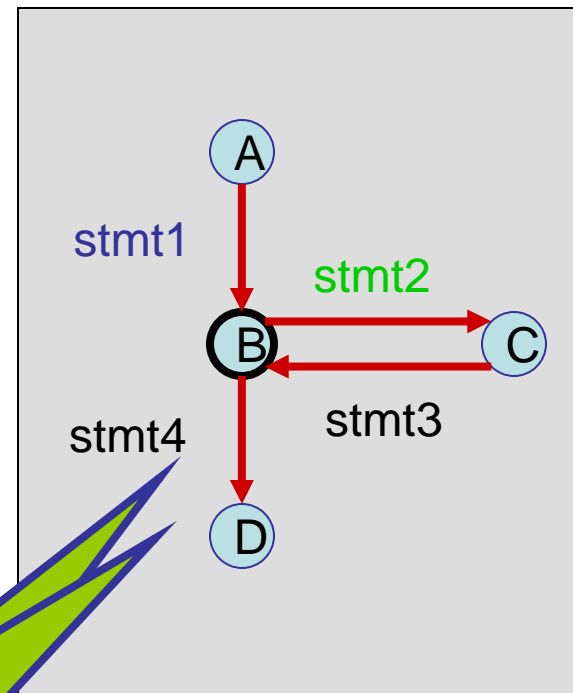

# What went Wrong?

---

- Consider all unrolled counterexamples at once
  - Convergence of abstraction discovery
- Inspect families of counterexamples of unbounded length
  - Justification for unbounded universal quantification
- Looking at one counterexample path at a time is too weak [JhalaMcMillan05,JhalaMcMillan06]

# Path Programs

- Treat **counterexamples** as **programs**
  - “Close” the loops

path program,  
contains **loops**,  
etc

# Meaning of Path Programs

---

Path program  $\hat{\cdot}$  (Possibly unbounded) **sets** of counterexamples:

- **Unbounded** counterexamples

- **Property-determined fragment** of original program
  - Can be analyzed independently to find good abstractions

# Path Invariants

---

- Invariant for path programs ` path invariant
- Abstraction refinement using path invariants
  - Elimination of **all** counterexamples **within** path program
  - Justification for **unbounded** quantification

# Invariant Generation

---

- Given a **path program**, with a designated **error** location, find an invariant that demonstrates **error** is not reachable
  - **Can scale**: Reduced obligation to program fragment
  - Outer model checking loop integrates path invariants into program invariant
- Can use any technique
- We use **constraint-based invariant generation**  
[SankaranarayananSipmaManna04, BeyerHenzingerM.Rybalchenko07]

# Technical Details

```

Example (1)
1) do {
    lock(A);
    old = new;
    q = q->next;
2) if (q != NULL) {
    callProc(q);
    new++;
3) } while (new != old);
4) unlock(A);
}
    
```

**Q. How to analyze recursive procedures ?**

```

Example (2)
1) do {
    lock(A);
    old = new;
    q = q->next;
2) if (q != NULL) {
    callProc(q);
    new++;
3) } while (new != old);
4) unlock(A);
}
    
```

# An example

---

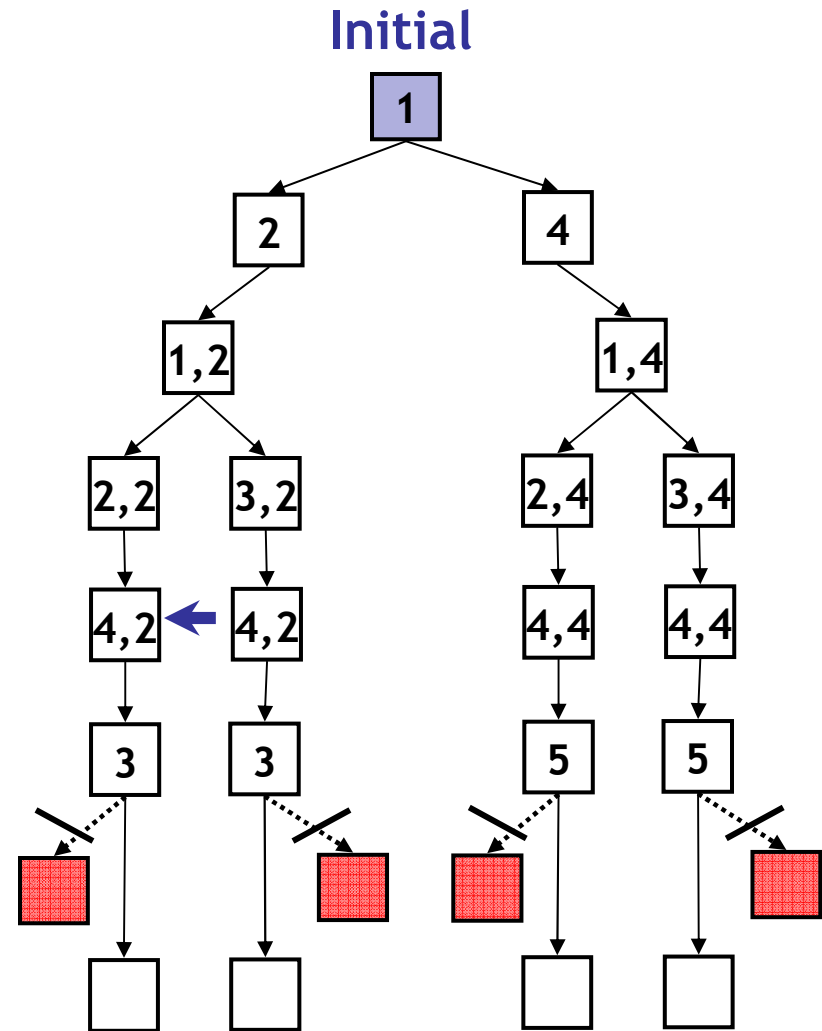

```
main() {  
    □  
    1: if (flag) {  
    2:     y = inc(x, flag);  
    3:     if (y <= x) ERROR;  
        } else {  
    4:     y = inc(z, flag);  
    5:     if (y >= z) ERROR;  
        }  
    □  
    return;  
}
```

```
inc(int a, int sign) {  
    1: if (sign) {  
    2:     rv = a+1;  
        } else {  
    3:     rv = a-1;  
        }  
    4: return rv;  
}
```

# Inline Calls in Reach Tree

```
main(){  
  □  
  1: if (flag){  
  2:   y = inc(x,flag);  
  3:   if (y<=x) ERROR;  
  } else {  
  4:   y = inc(z,flag);  
  5:   if (y>=z) ERROR;  
  }  
  □  
  return;  
}
```

```
inc(int a, int sign){  
  1: if (sign){  
  2:   rv = a+1;  
  } else {  
  3:   rv = a-1;  
  }  
  4: return rv;  
}
```

# Inline Calls in Reach Tree

## Problem

- Repeated analysis for “inc”
- Exploding call contexts

```
int x; //global
f1(){
  f2(){
    f3(){
      f4(){
        fn(){
          1: x ++;
          return;
        }
      }
    }
  }
}
```

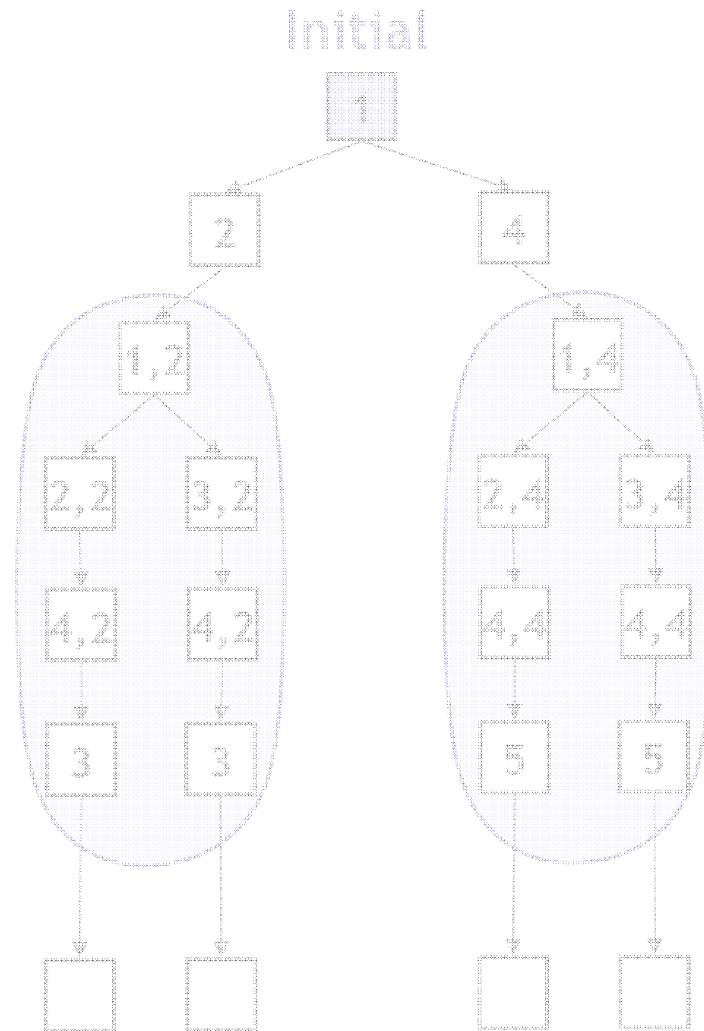

**2<sup>n</sup>** nodes in Reach Tree

# Inline Calls in Reach Tree

## Problem

- Repeated analysis for “inc”
- Exploding call contexts
- Cyclic call graph (Recursion)
  - **Infinite** Tree!

# Solution : Procedure Summaries

---

Summaries: Input/Output behavior

- Plug summaries in at each callsite  
... instead of inlining entire procedure

[Sharir-Pnueli 81, Reps-Horwitz-Sagiv 95]

- Summary = set of  $(F \square F')$ 
  - $F$  : Precondition formula describing input state
  - $F'$  : Postcondition formula describing output state

# Solution : Procedure Summaries

---

```
inc(int a, int sign){  
1: if (sign){  
2:   rv = a+1;  
   } else {  
3:   rv = a-1;  
   }  
4: return rv;  
}
```

- $(\neg \text{sign}=0 \sqcap rv > a)$
- $(\text{sign} = 0 \sqcap rv < a)$

- Summary = set of  $(F \sqcap F')$ 
  - $F$  : Precondition formula describing input state
  - $F'$  : Postcondition formula describing output state

**Q. How to compute, use summaries ?**

5) unlock ();
}
    
```

## Merging CEGAR and Abstract Domains

Refinement

Predicates:  $\text{LOCK}, \text{new} = \text{old}$

# Comparing dataflow and CEGAR

---

	<b>Dataflow</b>	<b>CEGAR with predicate abstraction</b>
Precision	- Propagates facts over infeasible branches	+ Analysis considers only feasible branches
	- Dataflow facts lost at join points	+ Path sensitive analysis considers each path independently

# Comparing dataflow and CEGAR

	<b>Dataflow</b>	<b>CEGAR with predicate abstraction</b>
Fact discovery	Eager Analysis + Quickly computes relevant facts  - Not adaptive, may become overwhelmed with irrelevant facts	Lazy Analysis  - Analysis expensive and predicates not always found  + Discovers relevant facts through counterexamples
Domain-specific analyses	+ Easily adapted, flexible representation of facts	- Predicates not convenient for domain-specific analyses

Can we combine the best of both approaches?

# Predicated lattices

---

- For each program location, track a set of first-order predicates over program variables
- Rather than track dataflow facts directly, track a *predicated lattice*:
  - New dataflow facts:
    - map: predicates  $\rightarrow$  original dataflow facts
  - Only join facts associated with the same set of predicates
  - Default predicate: `true`
- Instance of *reduced cardinal powers of lattices* [Cousot<sup>2</sup> 79]

# Example

---

1: `out = fopen(...);`

2: `fprintf(out, ...);`

3: `fclose(out);`

•  
•

true

out→0

true

out→C

# Example

4: flag = {0,1};

5: if (flag)

6: out = fopen(...);

7: else

;

.

Facts lost due to join

.

8: if (flag)

Add predicates:

flag!=0, flag==0

9: fprintf(out, ...);

true

out→C

true

out→0

flag==0

out→C

flag!=0

out→0

flag==0

out→C

flag!=0

out→0

# Symbolic execution lattice

---

- Tracks values of program variables and heap
  - Facts at each program point represented as map from *names* to *values*
  - *Symbolic execution* used to compute new facts after each statement
  - A “static” version of the DART algorithm

# Example

```
int x = 0;  
int y = 1;  
int *z;
```

```
if (*) {  
    z = &x;  
}  
else {  
    z = &y;  
}
```

```
...  
*z = 5;
```

```
...  
assert(*z == 5);
```

$x \rightarrow 0, y \rightarrow 1, z \rightarrow T$

$x \rightarrow 0, y \rightarrow 1, z \rightarrow x$

$x \rightarrow 0, y \rightarrow 1, z \rightarrow y$

$x \rightarrow 0, y \rightarrow 1, z \rightarrow \{x, y\} \Rightarrow T$

$x \rightarrow T, y \rightarrow T, z \rightarrow \{x, y\} \Rightarrow 5$

OK

---

How to extend this to liveness properties?

Specifically: Reasoning about termination

# When does a Program Terminate?

---

- Iff its **reachable transition relation** is **well-founded**
- Reachable transition relation =  
 $TR(x, x') \cap \text{Reach}(x) \times \text{Reach}(x')$  =  
Restriction of the transition relation to  
the set of reachable states

# Well-Founded Relation

---

- A binary relation  $>$  is *well-founded* if there is **no infinite descending sequence**
- No  $s_0, s_1, s_2, \dots$  such that  
 $s_0 > s_1 > s_2 > \dots$

Example:  $>$  on natural numbers

But not  $>$  on integers

# Idea: Rank Functions

---

- Fix a set  $X$ , and  $>$  a wf relation on  $X$
- Suppose I can map each **reachable** state  $s$  of the transition graph to a **rank**  $r(s) \in X$  s.t.  
 *$s \rightarrow s'$  implies  $r(s) > r(s')$*

Then the system must terminate

The converse is also true

# Example

---

Input  $x, n$

While( $x \leq n$ )  $x++$ ;

Terminates, using (roughly) the rank  
function  $n-x$

Does it, really?

# Disjunctive Rank Functions

---

- In many cases, finding a single wf relation can be difficult
- Suppose I can find wf relations  $T_1, \dots, T_k$  such that  $RTR \subseteq T_1 \cup \dots \cup T_k$
- Does the program terminate?
  - Not in general (Why?)

# Disjunctive Well-foundedness

---

If  $T_1 \dots T_k$  are wf relations and

$$R^+ \subseteq T_1 \cup \dots \cup T_k$$

Then:  $R$  is well-founded

Such  $R$  is called *disjunctively well-founded*

# Disjunctive Well-foundedness

---

*P terminates if  $TR \cap Reach \times Reach$  is disjunctively well-founded*

Useful: Can consider individual portions of the program independent of other parts

# Incremental Termination

---

$T = \text{emptyset}$

While  $TR^+$  not included in  $T$ :

invariant:  $T$  is a finite union of wf relations

find abstract counterexample to wf

if concretely feasible

does not terminate

otherwise find wf relation  $T'$

$T = T \cup T'$

# Counterexample to Termination

---

- Lasso = Stem + Cycle
    - Represents infinite execution
- Stem Cycle Cycle ...

Needs **rank-finding technique** to find a wf relation showing lasso cannot be executed arbitrarily (Heuristics exist)

# Reduction to Safety

---

- How to check if  $R^+ \subseteq T$  for the reachable transition relation?
- Can reduce check to safety
- Run program parallel with a monitor for T
  - runs in parallel with the program
  - inspects pairs of states wrt. T
  - goes to **error** if observes  $(s, s') \notin T$
  - Use non-determinism to perform check

# Reduction to Safety: Idea

---

selected :=  $\perp$

phase := **SELECT**

while True {

  switch (phase) {

**SELECT**: if ( nondet() ) {

      selected := current

      phase := **CHECK**

    }

**CHECK**: if ( (selected, current)  $\notin$  T ) { **ERROR**: }

  }

}

# Terminator

---

- Input: program written in C
- Language features supported
  - nested loops, gotos
  - aliasing
  - (mutually) recursive function calls
- Output:
  - termination proof: transition invariant
  - counterexample: lasso = stem + cycle
- Scalability: (on drivers from WinDDK)

# Questions?

---

# Lecture 4: Some Techniques for Infinite State

Rupak Majumdar

# Topics

---

1. Safety and liveness verification for **asynchronous programs**
  
1. Case splitting and symmetry reduction for **parameterized programs**

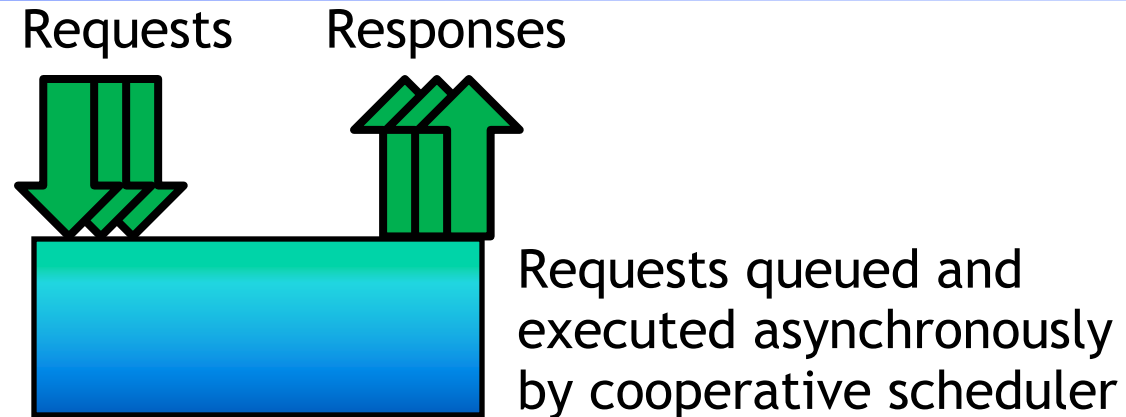

# Topic 1

---

Safety and liveness verification for  
**asynchronous programs**

# Asynchronous Programs

---

## Useful Model:

- Distributed Systems
- Web Servers
- Embedded Systems

## Languages and Libraries:

- LibAsync, LibEvent, ...
- NesC and TinyOS
- Go
- AJAX

# Asynchronous Programs

---

```
global bit b = 0;
```

```
main(){
```

```
...
```

```
  async h1();
```

```
...
```

```
}
```

```
h1(){
```

```
  if(b == 0){
```

```
    async h1();
```

```
    async h2();
```

```
  return;
```

```
}
```

```
}
```

```
h2(){
```

```
...
```

```
  b = 1;
```

```
...
```

```
  return;
```

```
}
```

- main ends in dispatch location
  - Calls asynchronously posted functions
- Async calls stored in task buffer
- Scheduler picks a pending task and runs it to completion

# Asynchronous Program Execution

```
global bit b = 0;
PC main(){
  ...
  async h1();
  ...
}
h1(){
  if(b == 0){
    async h1();
    async h2();
  }
  return;
}
h2(){
  ...
  b = 1;
  ...
  return;
}
```

- Execution starts in **main**
- Task buffer empty

Pending Calls  
h1

State: b = 0

# Asynchronous Program Execution

```
global bit b = 0;
```

```
main(){
```

```
...
```

```
  async h1();
```

```
  ...
```

```
}
```

```
h1(){
```

```
  if(b == 0){
```

```
    async h1();
```

```
    async h2();
```

```
  return;
```

```
}
```

```
}
```

```
h2(){
```

```
...
```

```
  b = 1;
```

```
  ...
```

```
  return;
```

```
}
```

- Execution enters dispatch loop
- Picks pending call and executes it
- Returns to dispatch loop on return

Pending Calls

h1

h2

State: b = 0

# Asynchronous Program Execution

```
global bit b = 0;
```

```
main(){
```

```
...
```

```
  async h1();
```

```
  ...
```

```
}
```

```
h1(){
```

```
  if(b == 0){
```

```
    async h1();
```

```
    async h2();
```

```
  return;
```

```
}
```

```
}
```

```
h2(){
```

```
...
```

```
  b = 1;
```

```
...
```

```
  return;
```

```
}
```

- Pick another pending call

Pending Calls

h1

h2

h1

h2

State: b = 0

# Asynchronous Program Execution

```
global bit b = 0;
```

```
main(){
```

```
...
```

```
  async h1();
```

```
  ...
```

```
}
```

```
h1(){
```

```
  if(b == 0){
```

```
    async h1();
```

```
    async h2();
```

```
  return;
```

```
}
```

```
}
```

```
h2(){
```

```
...
```

```
  b = 1;
```

```
...
```

```
  return;
```

```
}
```

- Pick some pending task

Pending Calls

h2

h1

h2

State: b = 1

# Asynchronous Program Execution

```
global bit b = 0;
```

```
main(){
```

```
...
```

```
  async h1();
```

```
  ...
```

```
}
```

```
h1(){
```

```
  if(b == 0){
```

```
    async h1();
```

```
    async h2();
```

```
  return;
```

```
}
```

```
}
```

```
h2(){
```

```
...
```

```
  b = 1;
```

```
...
```

```
  return;
```

```
}
```

- Pick some pending task

Pending Calls

h2

h1

State: b = 1

# Asynchronous Program Execution

```
global bit b = 0;
```

```
main(){
```

```
...
```

```
  async h1();
```

```
  ...
```

```
}
```

```
h1(){
```

```
  if(b == 0){
```

```
    async h1();
```

```
    async h2();
```

```
  return;
```

```
}
```

```
}
```

```
h2(){
```

```
...
```

```
  b = 1;
```

```
...
```

```
  return;
```

```
}
```

- And the program terminates

Pending Calls

h2

State: b = 1

# Observations

---

```
global bit b = 0;
```

```
main(){
```

```
...
```

```
  async h1();
```

```
...
```

```
}
```

```
h1(){
```

```
  if(b == 0){
```

```
    async h1();
```

```
    async h2();
```

```
  return;
```

```
}
```

```
}
```

```
h2(){
```

```
...
```

```
  b = 1;
```

```
...
```

```
  return;
```

```
}
```

- Call stack for a handler can be unbounded
- Shared global state can change between posting and execution
- Task Buffer can be unbounded
  - Consider  $n$  runs of  $h1$  before  $h2$
  - Task buffer contains  $n$   $h1$ ,  $1$   $h2$

# Properties: Safety

---

```
global bit b = 0;
```

```
main(){
```

```
...
```

```
  async h1();
```

```
...
```

```
}
```

```
h1(){
```

```
  if(b == 0){
```

```
    async h1();
```

```
    async h2();
```

```
    return;
```

```
  }
```

```
}
```

```
h2(){
```

```
...
```

```
  b = 1;
```

```
...
```

```
  return;
```

```
}
```

Given a **Boolean** asynchronous program and a control location in a handler

Is there an execution which reaches the control location?

We do not care about the task buffer

- Handlers cannot take decisions based on the contents of the task buffer

# Properties: Termination

---

```
global bit b = 0;
```

```
main(){
```

```
...
```

```
  async h1();
```

```
...
```

```
}
```

```
h1(){
```

```
  if(b == 0){
```

```
    async h1();
```

```
    async h2();
```

```
  return;
```

```
}
```

```
}
```

```
h2(){
```

```
...
```

```
  b = 1;
```

```
...
```

```
  return;
```

```
}
```

Given a **Boolean** asynchronous program,  
Does it terminate?

- main *does not* terminate on all runs
  - What if h1 is chosen over h2 forever?

# Fairness

---

```
global bit b = 0;

main(){
  ...
  async h1();
  ...
}

h1(){
  if(b == 0){
    async h1();

    async h2();

    return;
  }
}

h2(){
  ...
  b = 1;
  ...
  return;
}
```

An infinite execution is *fair* if

- For every handler  $h$  that is pending
- The scheduler eventually picks and runs an instance of  $h$
  
- So: the run choosing  $h_1$  over  $h_2$  always is not fair
  
- Will focus on *fair runs*
  - *Captures the intuition that scheduling is fair*

# Asynchronous Program Analysis

---

Main Result:

**Safety and Liveness decidable for asynchronous programs**

[SenViswanathan06, JhalaM07, GantyMRybalchenko09, GantyM09]

**This is hard because:** Not finite state or context free:

- potentially unbounded **stacks**,
- potentially unbounded **request queue**

**This is useful because:**

- Asynchronous programs used in many correctness-critical settings
- The style breaks up control flow, making it difficult to reason about code

# First Attempt: Does not Work

---

- Treat asynchronous calls as synchronous and use interprocedural reachability
- Why?
  - Global state can change between posting a task and executing it

# First Attempt: Does not Work

---

```
global bit b = 0;

main(){
  ...
  b = 0;
  async p1(); async p2();
}
```

```
p1(){
  assert(b==0);
}
```

```
p2(){
  b = 1;
  return;
}
```

- In synchronous computation, the assert holds
- In asynchronous computation, p2 can execute before p1

# Second Attempt

---

```
global bit b = 0;
main(){
  ...
  async h1();
  ...
}
h1(){
  if(b == 0){
    async h1();

    async h2();

    return;
  }
}
h2(){
  ...
  b = 1;
  ...
  return;
}
```

Reduce to sequential analysis

- Add a *counter* for each handler (tracks number of pending instances)
- An *async call increments counter*
- Dispatch loop chooses a non-zero counter, *decrements it and runs corresponding handler*

# Second Attempt

```
global bit b = 0;
        ch1=0, ch2=0;
main(){
    ...
    ch1++;

    while(ch1>0 || ch2>0){
        pick h s.t. ch > 0
        ch--;
        h();
    }
}
h1(){
    if(b == 0){
        ch1++;
        ch2++;
        return;
    }
}
h2(){
    ...
    b = 1;
    ...
    return;
}
```

Reduce to sequential analysis

- Add a *counter* for each handler (tracks number of pending instances)
- An *async call increments counter*
- Dispatch loop chooses a non-zero counter, *decrements it and runs corresponding handler*
- Sound, but decidability not obvious
  - In general, analyses undecidable for sequential programs with counters

# Technique

---

1. Convert an AP to one without recursion
2. Convert recursion-free AP to Petri nets

# Removing the Stack

---

- Need to summarize the effect of handlers on the task buffer
  - Observation: Just the *number* of async calls matter, *not the order* in which they are made
- Parikh's Lemma: For every *context free* language  $L$ , there is a *regular* language  $L'$  such that:
  - For every  $w$  in  $L$ , there is a permutation of  $w$  in  $L'$  and conversely
- So: can replace a recursive handler with a non-recursive one while maintaining the summary

# Example

---

```
H() {  
  if (*) {  
    async a();  
    H();  
    async b()  
  }  
}
```

```
H() {  
  while (*) {  
    async a();  
    async b();  
  }  
}
```

This gets rid of unbounded stacks in handlers  
From now on, only consider *recursion-free AP*

But there is a second source of unboundedness (the task buffer)

# Petri Nets

---

Can convert an asynchronous program into a *Petri net (PN)* s.t. every execution of the async program is equivalent to an execution of the Petri net

In particular:

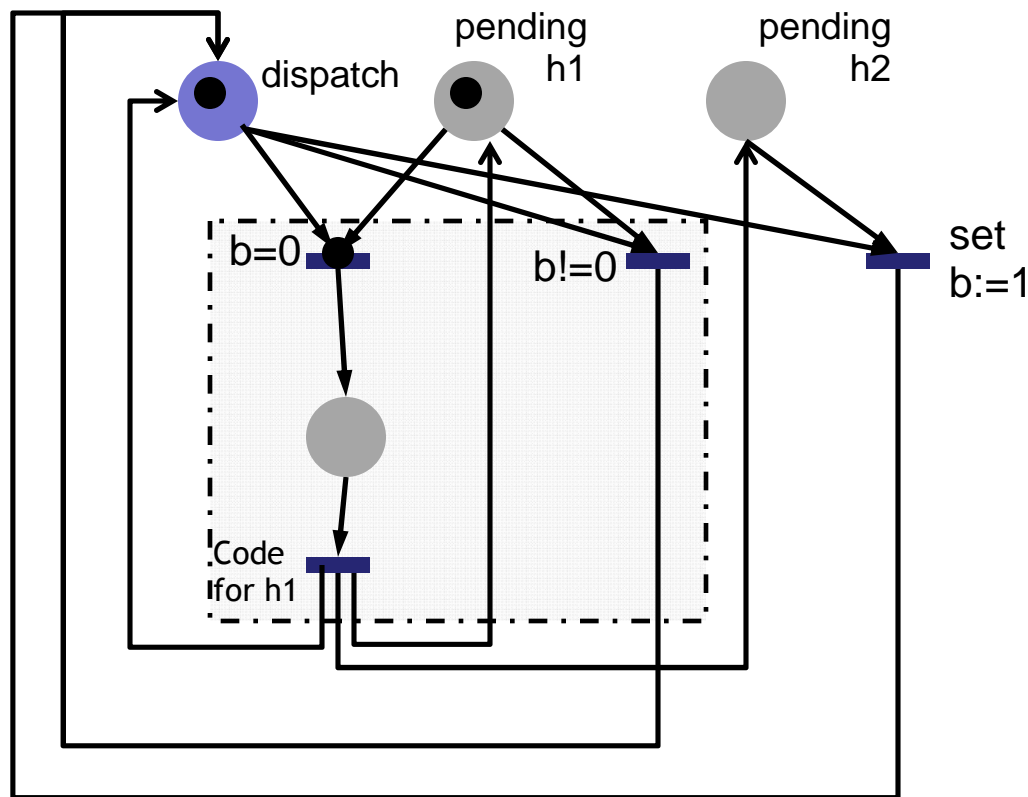

- The asynchronous program is **safe** iff the Petri net is **coverable**
- The asynchronous program **fairly terminates** iff the Petri net **has no fair infinite runs**

# Petri Nets 101

- Set of places 
- Set of transitions 
- Places marked with tokens 
- Transition function takes tokens from sources of transitions to destinations
- With an initial marking, defines an infinite state system
- But with good decidability properties

# Petrification

```
global bit b = 0;
```

```
main(){
```

```
...
```

```
  async h1();
```

```
...
```

```
}
```

```
h1(){
```

```
  if(b == 0){
```

```
    async h1();
```

```
    async h2();
```

```
  return;
```

```
}
```

```
}
```

```
h2(){
```

```
...
```

```
  b = 1;
```

```
...
```

```
  return;
```

```
}
```

Tokens:

- Control flow in each handler
- Pending handler calls

# That's Good, Because...

---

Can apply algorithmic results on Petri Nets  
to reason about async programs

- Many strong decidability results

# Coverability Problem for PN

---

- Given Petri net  $P$ 
  - (Places, transitions, initial marking)
- Target marking  $m$ 
  - Places of  $P$   $\rightarrow$  tokens
- Is there an execution of  $P$  to a marking  $m'$  with  $m \leq m'$  ?
  - $m \leq m'$  if  $m(p) \leq m'(p)$  for each place

# Karp Miller Tree

- Build a tree with markings as nodes
- Transitions as edges
- Infinite tree
- But accelerate
- Terminates by **Dickson's Lemma**

# Safety Verification

---

Corollary to Coverability Graph: **Safety verification decidable**

- Remove recursion using Parikh's lemma
- Build Petri net, construct coverability tree
- Check if there is a node in the coverability tree with a non-zero entry in the special location
- Similar proof in [SenViswanathan06] using multiset rewrite systems
- Independent, alternate algorithm in [JhalaM07]

# Boundedness Verification

---

An AP is **bounded** if there is some  $N$  such that the task buffer always has fewer than  $N$  tasks

Reduce to checking **boundedness of PN**

- Algorithm based on coverability tree construction

# Fair Termination

---

- Given:
  - An asynchronous program with **Boolean variables**
- Check:
  - There is no fair infinite run
- Two checks:
  - (a) Each called handler terminates  LTL model checking for pushdown systems [Walukiewicz, Steffen]
  - (b) There is no infinite fair execution of handlers

# Hardness: PN Reachability

---

- Given Petri net  $P$ 
  - (Places, transitions, initial marking)
- Target marking  $m$ 
  - Places of  $P$   $\rightarrow$  tokens
- Is there an execution of  $P$  to marking  $m$ ?
- Known: Decidable, EXPSPACE-hard
- Best known algorithms: non-primitive recursive space

# From FT to PN Reachability

---

- Given PN and place  $p$ , construct AP such that AP has fair infinite run iff PN reaches a marking where  $p$  has no tokens
  - Known to be equivalent to PN reachability
- Simulate a PN using an AP
  - One task for each place
  - One task to simulate transitions
- Post a task to guess when  $p$  has no tokens

# Idea of Reduction

---

- Simulate a PN using an AP
  - One task for each place
  - One task to simulate transitions
- Post a task to guess when p has no tokens
  - If task for p is scheduled after guess, then guess was wrong, so shut down program
  - Otherwise execute a simple infinite loop

Fairness ensures the guess is eventually made and eventually falsified (if wrong)

# Fair Termination is Decidable

---

- First part the same:
  - Remove stack using Parikh's lemma
  - Construct Petri net
- Use a logic over Petri nets [Yen90] to encode the fairness condition
  - Complexity of the logic: polynomial reduction to PN reachability
  - Note: Original paper [Yen90] had a mistake

# Main Result

---

Theorem: [GantyM.09]

*Checking safety and fair termination is decidable for asynchronous programs*

*Safety EXPSPACE-complete for asynchronous automata*

- Using a more careful construction

# Observations

---

- For async programs, fair termination computable
  - Unlike threads [Ramalingam 00]
  - Known that threads and events are **dual** [NeedhamLauer]
  
  - So what gives?
  - We restrict global state to be finite!
  - A thread can encode unbounded information in its stack

# Topic 2

---

## Parameterized Verification of Software

# A Simple Example

---

- Global int ctr = 0;
- Arbitrary number of threads
- Each thread executes:  
    ctr = ctr + 1;  
    assert (ctr > 0)  
    ctr = ctr - 1;

Show assertion holds

# Parameterized Verification

---

- Intuitively, the assertion holds
- For any fixed number  $N$  of threads, can prove the assertion by finite state model checking
  - Ctr bounded by  $N$
- How can we prove the system for *any number of threads*?

# Idea: Temporal Case Splitting

---

- To show the property for all threads,
  - fix an arbitrary thread, and
  - prove the property for that thread
- Abstraction: Consider thread  $tid$ , and environment “not  $tid$ ” for all threads whose id is not  $tid$
- In general, has Skolem variables and abstract system into Skolems and others

# Conclusion

---

# Verification by Theorem Proving

---

```
Example ( ) {  
1: do{  
    lock();  
    old = new;  
    q = q->next;  
2:   if (q != NULL){  
3:     q->data = new;  
     unlock();  
     new ++;  
   }  
4: } while(new != old);  
5: unlock ();  
   return;  
}
```

1. Loop Invariants
2. Logical formula
3. Check Validity

Invariant:

$lock \wedge new = old$

✓

$\neg lock \wedge new \neq old$

# Verification by Theorem Proving

---

```
Example ( ) {
1: do{
    lock();
    old = new;
    q = q->next;
2:   if (q != NULL){
3:     q->data = new;
    unlock();
    new ++;
  }
4: } while(new != old);
5: unlock ();
   return;
}
```

1. Loop Invariants

# Toward More Reliable Systems

---

- **Tools** and **theory** are equally important
  - Tools reinforce process change, amplify programmer productivity, ensure quality
  - Theoretical progress drives better tools
  - Applications motivate good theory
- System development is too complex to be reduced to a single problem or solution
  - Model checking is not the only tool
  - Just tools will not make software perfect
  - How can developers and verifiers interact better?

# Conclusions

---

- Software systems need to be more reliable
  - Enormous resources spent in stabilizing software
- Long way to go
  - Inadequate languages, inaccurate tools
  - Make system developers and system verifiers interact
- Tools, by themselves, are not enough
  - Tools and analysis is one view, but social aspects are also important

# Thank You!

---
