

NPTEL MOOC, JAN-FEB 2015
Week 7, Module 6

DESIGN AND ANALYSIS OF ALGORITHMS

Matrix Multiplication

MADHAVAN MUKUND, CHENNAI MATHEMATICAL INSTITUTE
<http://www.cmi.ac.in/~madhavan>

Multiplying matrices

- * To multiply matrices A and B , need compatible dimensions
 - * A of dimension $m \times n$, B of dimension $n \times p$
 - * AB has dimension mp
- * Each entry in AB take $O(n)$ steps to compute
 - * $AB[i,j]$ is $A[i,1]B[1,j] + A[i,2]B[2,j] + \dots + A[i,n]B[n,j]$
- * Overall, computing AB is $O(mnp)$

Multiplying matrices

- * Matrix multiplication is associative
 - * $ABC = (AB)C = A(BC)$
 - * Bracketing does not change the answer ...
 - * ... but can affect the complexity of computing it!

Multiplying matrices

- * Suppose dimensions are $A[1,100]$, $B[100,1]$, $C[1,100]$
 - * Computing $A(BC)$
 - * BC is $[100,100]$, $100 \times 1 \times 100 = 10000$ steps
 - * $A(BC)$ is $[1,100]$, $1 \times 100 \times 100 = 10000$ steps
 - * Computing $(AB)C$
 - * AB is $[1,1]$, $1 \times 100 \times 1 = 100$ steps
 - * $(AB)C$ is $[1,100]$, $1 \times 1 \times 100 = 100$ steps
- * $A(BC)$ takes 20000 steps, $(AB)C$ takes 200 steps!

Multiplying matrices

- * Given matrices M_1, M_2, \dots, M_n of dimensions $[r_1, c_1], [r_2, c_2], \dots, [r_n, c_n]$
- * Dimensions match, so $M_1 \times M_2 \times \dots \times M_n$ can be computed
- * $c_i = r_{i+1}$ for $1 \leq i < n$
- * Find an optimal order to compute the product
 - * That is, bracket the expression optimally

Inductive structure

- * Product to be computed: $M_1 \times M_2 \times \dots \times M_n$
- * Final step would have combined two subproducts
 - * $(M_1 \times M_2 \times \dots \times M_k) \times (M_{k+1} \times M_{k+2} \times \dots \times M_n)$, for some $1 \leq k < n$
 - * First factor has dimension (r_1, c_k) , second (r_{k+1}, c_n)
 - * Final multiplication step costs $O(r_1 c_k c_n)$
 - * Add cost of computing the two factors

Subproblems

- * Final step is $(M_1 \times M_2 \times \dots \times M_k) \times (M_{k+1} \times M_{k+2} \times \dots \times M_n)$
- * Subproblems are $(M_1 \times M_2 \times \dots \times M_k)$ and $(M_{k+1} \times M_{k+2} \times \dots \times M_n)$
- * Total cost is $\text{Cost}(M_1 \times M_2 \times \dots \times M_k) + \text{Cost}(M_{k+1} \times M_{k+2} \times \dots \times M_n) + r_1 C_k C_n$
- * Which k should we choose?
- * No idea! Try them all and choose the minimum!

Inductive formulation

- * $\text{Cost}(M_1 \times M_2 \times \dots \times M_n) =$
minimum value, for $1 \leq k < n$, of
$$\text{Cost}(M_1 \times M_2 \times \dots \times M_k) +$$
$$\text{Cost}(M_{k+1} \times M_{k+2} \times \dots \times M_n) +$$
$$r_1 C_k C_n$$
- * When we compute $\text{Cost}(M_1 \times M_2 \times \dots \times M_k)$ we will get subproblems of the form $M_j \times M_{j+1} \times \dots \times M_k$

In general ...

* $\text{Cost}(M_i \times M_{i+1} \times \dots \times M_j) =$

minimum value, for $i \leq k < j$, of

$\text{Cost}(M_i \times M_{i+1} \times \dots \times M_k) +$

$\text{Cost}(M_{k+1} \times M_{k+2} \times \dots \times M_j) +$

$r_i c_k c_j$

* Write $\text{Cost}(i,j)$ to denote $\text{Cost}(M_i \times M_{i+1} \times \dots \times M_j)$

Final equation

- * $\text{Cost}(i,i) = 0$ — No multiplication to be done
- * $\text{Cost}(i,j) = \min \text{ over } i \leq k < j$
[$\text{Cost}(i,k) + \text{Cost}(k+1,j) + r_i c_k c_j$]
- * Note that we only require $\text{Cost}(i,j)$ when $i \leq j$

Subproblem dependency

- * $\text{Cost}(i,j)$ depends on $\text{Cost}(i,k)$, $\text{Cost}(k+1,j)$ for all $i \leq k < j$
- * Can have $O(n)$ dependent values, unlike LCS, LCW, ED
- * Start with main diagonal and fill matrix by columns, bottom to top, left to right

	1	...	i	...	j	...	n

MMCost(M1,...,Mn), DP

```
function MMC(R,C)
```

```
# R[1..n],C[1..n] have row/column sizes
```

```
for r = 1,...,n
```

```
    MMC[r][r] = 0
```

```
for c = 2,3,...,n+1
```

```
    for r = c,c-1,...,1
```

```
        MMC[r][c] = infinity
```

```
        for k = r,r+1,...,c-1
```

```
            subprob = MMC[r][k] + MMC[k][c] +  
                    R[r]C[k]C[c]
```

```
            if (subprob < MMC[r][c])
```

```
                MMC[r][c] = subprob
```

Complexity

- * As with LCS, ED, we to fill an $O(n^2)$ size table
- * However, filling $MMC[i][j]$ could require examining $O(n)$ intermediate values
- * Hence, overall complexity is $O(n^3)$
