Class hierarchy

- Subclasses inherit attributes from parent class
- Subclasses can add functionality
 - A subclass is more specific than its parent
 - Subclasses can be used in place of the parent class

```
class Employee {...}
```

```
class Manager extends Employee{
    private String secretary;
    public boolean setSecretary(name s){ ... }
    public String getSecretary(){ ... }
}
```

```
Employee e = new Manager()
```

Overriding and dynamic dispatch

- Subclass can override parent class method
 - Function name and signature must both match
 - public equals(Date d) does not override public equals (Object o)
- Dynamic dispatch allows each object to "know" which method to use.

```
class Employee { ... public double bonus(double p) ...}
class Manager extends Employee{
   ... public double bonus(double p) ...
}
Employee e = new Manager();
...
print(e.bonus(x));
```

Java class hierarchy

- No multiple inheritance tree-like
- Universal superclass Object
- Useful methods defined in Object

boolean equals(Object o) // defaults to pointer equality

String toString()

// converts the values of the
// instance variable to String

To print o, use System.out.println(o+"");

Subclasses, subtyping and inheritance

Class hierarchy provides both subtyping and inheritance

Subtyping

- Compatibility of interfaces.
- B is a subtype of A if every function that can be invoked on an object of type A can also be invoked on an object of type B.

Inheritance

- Reuse of implementations.
- B inherits from A if some functions for B are written in terms of functions of A.

Consider the following classes

- queue, with methods insert-rear, delete-front
- stack, with methods insert-front, delete-front
- deque, with methods insert-front, delete-front, insert-rear, delete-rear

Consider the following classes

- queue, with methods insert-rear, delete-front
- stack, with methods insert-front, delete-front
- deque, with methods insert-front, delete-front, insert-rear, delete-rear

What are the subtype and inheritance relationships between these classes?

- queue, with methods insert-rear, delete-front
- stack, with methods insert-front, delete-front
- deque, with methods insert-front, delete-front, insert-rear, delete-rear

- queue, with methods insert-rear, delete-front
- stack, with methods insert-front, delete-front
- deque, with methods insert-front, delete-front, insert-rear, delete-rear

Subtyping

- deque has more functionality than queue or stack
- deque is a subtype of both these types

- queue, with methods insert-rear, delete-front
- stack, with methods insert-front, delete-front
- deque, with methods insert-front, delete-front, insert-rear, delete-rear

Subtyping

- deque has more functionality than queue or stack
- deque is a subtype of both these types

Inheritance

- Can suppress two functions in a deque and use it as a queue or stack
- Both queue and stack inherit from deque

Subclasses, subtyping and inheritance

- Class hierarchy provides both subtyping and inheritance
- Subtyping
 - Compatibility of interfaces.
 - B is a subtype of A if every function that can be invoked on an object of type A can also be invoked on an object of type B.

Inheritance

- Reuse of implementations.
- B inherits from A if some functions for B are written in terms of functions of A.

Using one idea (hierarchical classes) to implement both concepts blurs the distinction between the two

Abstract classes

- Collect together classes under a common heading
- Classes Circle, Square and Rectangle are all shapes
- Create a class Shape so that Circle, Square and Rectangle extend Shape

Abstract classes

- Collect together classes under a common heading
- Classes Circle, Square and Rectangle are all shapes
- Create a class Shape so that Circle, Square and Rectangle extend Shape
- We want to force every shape to define a function public double perimeter()

Abstract classes

- Collect together classes under a common heading
- Classes Circle, Square and Rectangle are all shapes
- Create a class Shape so that Circle, Square and Rectangle extend Shape
- We want to force every shape to define a function public double perimeter()
 - Define a function in Shape that returns an absurd value public double perimeter() { return -1.0; }
 - Rely on the subclass to redefine this function

Abstract classes . . .

- A better solution
 - Provide an abstract definition in Shape

```
public abstract double perimeter();
```

Forces subclasses to provide a concrete implementation

Abstract classes . . .

- A better solution
 - Provide an abstract definition in Shape

```
public abstract double perimeter();
```

- Forces subclasses to provide a concrete implementation
- Cannot create objects from a class that has abstract functions
- Shape must itself be declared to be abstract

```
abstract class Shape{
    ...
    public abstract double perimeter();
    ...
}
```

Abstract classes . . .

Can still declare variables whose type is an abstract class Shape sarr[] = new Shape[3];

```
Circle c = new Circle(...); sarr[0] = c;
Square s = new Square(...); sarr[1] = s;
Rectangle r = new Rectangle(...); sarr[2] = r;
```

```
for (i = 0; i < 2; i++){
   size = sarr[i].perimeter();
        // each sarr[i] calls the appropriate method
   ...
}</pre>
```

Generic functions

Use abstract classes to specify generic properties

```
abstract class Comparable{
  public abstract int cmp(Comparable s);
    // return -1 if this < s, 0 if this == 0,
    // +1 if this > s
}
```

Generic functions

Use abstract classes to specify generic properties

```
abstract class Comparable{
  public abstract int cmp(Comparable s);
    // return -1 if this < s, 0 if this == 0,
    // +1 if this > s
}
```

Now we can sort any array of objects that extend Comparable

```
class Sortfunctions{
  public static void quicksort(Comparable[] a){
    ...
    // Usual code for quicksort, except that
    // to compare a[i] and a[j] we use a[i].cmp(a[j])
  }
}
```

Generic functions ...

```
class Sortfunctions{
      public static void quicksort(Comparable[] a){
        • • •
To use this definition of quicksort, we write
    class Myclass extends Comparable{
      double size; // quantity used for comparison
      • • •
      public int cmp(Comparable s){
        if (s instanceof Myclass){
          // compare this.size and ((Myclass) s).size
          // Note the cast to access s.size
           • • •
```

- How do can we sort Circle objects?
 - Circle already extends Shape
 - Java does not allow Circle to also extend Comparable!

- How do can we sort Circle objects?
 - Circle already extends Shape
 - Java does not allow Circle to also extend Comparable!
- An interface is an abstract class with no concrete components

```
interface Comparable{
   public abstract int cmp(Comparable s);
}
```

- How do can we sort Circle objects?
 - Circle already extends Shape
 - Java does not allow Circle to also extend Comparable!
- An interface is an abstract class with no concrete components

```
interface Comparable{
   public abstract int cmp(Comparable s);
}
```

A class that extends an interface is said to "implement" it:

```
class Circle extends Shape implements Comparable{
   public double perimeter(){...}
   public int cmp(Comparable s){...}
   ...
}
```

- How do can we sort Circle objects?
 - Circle already extends Shape
 - Java does not allow Circle to also extend Comparable!
- An interface is an abstract class with no concrete components

```
interface Comparable{
   public abstract int cmp(Comparable s);
}
```

A class that extends an interface is said to "implement" it:

```
class Circle extends Shape implements Comparable{
   public double perimeter(){...}
   public int cmp(Comparable s){...}
   ...
}
```

Can implement multiple interfaces
